Chapter 1 About This Document

This document describes installing and using Tectia Client. This manual is meant for Tectia Client users and administrators who install and configure the software.

This document contains the following information:

- Installing Tectia Client
- Getting started
- Authentication
- Transferring files
- Tunneling
- Troubleshooting
- Appendices, including command-line tool, GUI, and audit message references

The Connection Broker handles all cryptographic operations and authentication-related tasks for Tectia Client. In addition, Tectia Client is configured through the Connection Broker settings made either in an XML file, or in the Tectia Connections Configuration GUI as described in Section A.1.

For general information on Tectia Client and its features, refer to Tectia Client/Server Product Description.

1.1 Documentation Conventions

The following typographical conventions are used in Tectia documentation:

Table 1.1. Documentation conventions

<table>
<thead>
<tr>
<th>Convention</th>
<th>Usage</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bold</td>
<td>Tools, menus, GUI elements and commands, command-line tools, strong emphasis</td>
<td>Click <strong>Apply</strong> or <strong>OK</strong>.</td>
</tr>
</tbody>
</table>
Chapter 1 About This Document

<table>
<thead>
<tr>
<th>Convention</th>
<th>Usage</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>⏳</td>
<td>Series of menu selections</td>
<td>Select File → Save</td>
</tr>
<tr>
<td><strong>Monospace</strong></td>
<td>Command-line and configuration options, file names and directories, etc.</td>
<td>Refer to readme.txt</td>
</tr>
<tr>
<td><em>Italics</em></td>
<td>Reference to other documents or products, URLs, emphasis</td>
<td>See Tectia Client User Manual</td>
</tr>
<tr>
<td><strong>Monospace</strong></td>
<td>Replaceable text or values</td>
<td>rename oldfile newfile</td>
</tr>
<tr>
<td><em>Italics</em></td>
<td>In front of a command, # indicates that the command is run as a privileged user (root).</td>
<td># rpm --install package.rpm</td>
</tr>
<tr>
<td>$</td>
<td>In front of a command, $ indicates that the command is run as a non-privileged user.</td>
<td>$ sshg3 user@host</td>
</tr>
<tr>
<td>\</td>
<td>At the end of a line in a command, \ indicates that the command continues on the next line, but there was not space enough to show it on one line.</td>
<td>$ ssh-keygen-g3 -t rsa \ -F -c mykey</td>
</tr>
</tbody>
</table>

### Note

A Note indicates neutral or positive information that emphasizes or supplements important points of the main text. Supplies information that may apply only in special cases (for example, memory limitations, equipment configurations, or specific versions of a program).

### Caution

A Caution advises users that failure to take or to avoid a specified action could result in loss of data.

#### 1.1.1 Operating System Names

When the information applies to several operating systems versions, the following naming systems are used:

- **Unix** refers to the following supported operating systems:
  - HP-UX
  - IBM AIX
  - Red Hat Linux, SUSE Linux
  - Linux on IBM System z
• Solaris

• IBM z/OS, when applicable; as Tectia Server for IBM z/OS is running in USS and uses Unix-like tools.

• z/OS is used for IBM z/OS, when the information is directly related to IBM z/OS versions.

• Windows refers to all supported Windows versions.

### 1.1.2 Directory Paths

The following conventions are used in the documentation to refer to directory paths:

$HOME

A Unix environment variable, that indicates the path to the user's home directory.

%APPDATA%

A Windows environment variable, that indicates the path to the user-specific Application Data folder. By default expands to:

"C:\Documents and Settings\<username>\Application Data" on pre-Vista Windows versions

"C:\Users\<username>\AppData\Roaming" on Windows Vista and later.

%USERPROFILE%

A Windows environment variable, that indicates the path to the user-specific profile folder. By default expands to:

"C:\Documents and Settings\<username>" on pre-Vista Windows versions

"C:\Users\<username>" on Windows Vista and later.

<INSTALLDIR>

Indicates the default installation directory on Windows:

"C:\Program Files\SSH Communications Security\SSH Tectia" on 32-bit Windows versions

"C:\Program Files (x86)\SSH Communications Security\SSH Tectia" on 64-bit Windows versions

### 1.2 Customer Support

All Tectia product documentation is available at [https://www.ssh.com/manuals/](https://www.ssh.com/manuals/).

FAQ with how-to instructions for all Tectia products are available at [http://answers.ssh.com/](http://answers.ssh.com/).
If you have purchased a maintenance agreement, you are entitled to technical support from SSH Communications Security. Review your agreement for specific terms and log in at https://support.ssh.com/.

Information on submitting support requests, feature requests, or bug reports, and on accessing the online resources is available at https://support.ssh.com/.

### 1.3 Component Terminology

The following terms are used throughout the documentation.

**client computer**

The computer from which the Secure Shell connection is initiated.

**Connection Broker**

The Connection Broker is a component included in Tectia Client, and in the Tectia Server for IBM z/OS client tools. Connection Broker handles all cryptographic operations and authentication-related tasks.

**host key pair**

A public-key pair used to identify a Secure Shell server. The private key file is accessible only to the server. The public key file is distributed to users connecting to the server.

**remote host**

Refers to the other party of the connection, client computer or server computer, depending on the viewpoint.

**Secure Shell client**

A client-side application that uses the Secure Shell version 2 protocol, for example sshg3, sftpg3, or scp3 of Tectia Client.

**Secure Shell server**

A server-side application that uses the Secure Shell version 2 protocol.

**server computer**

The computer on which the Secure Shell service is running and to which the Secure Shell client connects.

**SFTP server**

A server-side application that provides a secure file transfer service as a subsystem of the Secure Shell server.

**Tectia Client**

A software component installed on a workstation. Tectia Client provides secure interactive file transfer and terminal client functionality for remote users and system administrators to access and manage servers running Tectia Server or other applications using the Secure Shell protocol. It also supports (non-transparent) static tunneling.
Tectia client/server solution

The Tectia client/server solution consists of Tectia Client, Tectia Server, and Tectia Server for IBM z/OS (including the Tectia Server for IBM z/OS client tools).

Tectia Connections Configuration GUI

Tectia Client has a graphical user interface for configuring the connection settings to remote servers. The GUI is supported on Windows and Linux.

Tectia Secure File Transfer GUI

Tectia Client on Windows includes a separate graphical user interface (GUI) for handling and performing file transfers interactively.

Tectia Server

Tectia Server is a server-side component where Secure Shell clients connect to. There are three versions of the Tectia Server product available: Tectia Server for Linux, Unix and Windows platforms, Tectia Server for Linux on IBM System z, and Tectia Server for IBM z/OS.

Tectia Server for IBM z/OS

Tectia Server for IBM z/OS provides normal Secure Shell connections and supports the enhanced file transfer (EFT) features and transparent TCP tunneling on IBM mainframes.

Tectia Server for Linux on IBM System z

Tectia Server for Linux on IBM System z provides Secure Shell connections on Linux running on IBM System z platforms.

Tectia Server Configuration tool

Tectia Server has a graphical user interface that can be used to configure the server instead of editing the configuration file. The GUI is supported on Windows.
	ransparent FTP tunneling

An FTP connection transparently encrypted and secured by a Secure Shell tunnel.

transparent TCP tunneling

A TCP application connection transparently encrypted and secured by a Secure Shell tunnel.

tunneled application

A TCP application secured by a Secure Shell connection.

user key pair

A public-key pair used to identify a Secure Shell user. The private key file is accessible only to the user. The public key file is copied to the servers the user wants to connect to.
Chapter 2 Installing Tectia Client

This chapter gives instructions on installing (and removing) Tectia Client for each supported platform, and lists the locations of the Tectia files.

2.1 Preparing for Installation

This section lists the supported platforms and the prerequisites for the Tectia Client installation.

2.1.1 System Requirements

Check the following table for the operating systems supported as Tectia Client platforms:

Table 2.1. Supported operating systems for Tectia Client and Server

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Client</th>
<th>Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>HP-UX (PA-RISC)</td>
<td>11i v1, 11i v2, 11i v3</td>

</tr>
</tbody>
</table>
Chapter 2 Installing Tectia Client

Operating System | Client | Server
--- | --- | ---

Oracle Linux with Unbreakable Enterprise Kernel is also supported.

**Note**

Keep the operating system fully patched according to recommendations by the operating system vendor.

The supported operating systems are required to have the following or superseding patches or maintenance levels installed. Tectia solutions have been tested with the following patches and maintenance levels:

- IBM AIX 6.1, 7.1, 7.2: APARs IJ04641 and IJ06228 (fix to a bug (reference #: 0729357) that causes Tectia to hang on AIX).
- IBM AIX 6.1: Technology level 3 (fix to AIX bug IDs IZ46727 and IZ17492). Note that these fixes are also available as service packs for some earlier technology levels.
- IBM AIX requires the following updated C++ runtime libraries:
  - Fileset update: bos.rte.libc 5.3.8.1
  - Fileset update: bos.rte.security 5.3.8.1
  - Base level update: xlC.rte 10.1.0.0
- Red Hat Enterprise Linux 4 and 5: xorg-x11-xauth is required for X11 forwarding
- SUSE Linux Enterprise Server 10: Service pack 1

**HP-UX patches**

The general principle is to install the latest **HP-required patch bundle** for the OS version, currently required bundles exist for 11i v1 and 11i v2. Proper functioning of the Tectia software also requires the latest **HP recommended patches** for libc, pthread and linker tools. In addition, some individual patches may be needed to fix specific problems. Such patches are mentioned separately.

**Note**

Check the HP web-site for any newer patches superseding the ones listed here. We recommend installing the latest version recommended by HP.

- HP-UX 11i v1 on PA-RISC requires the following patches:
  - B.11.11.0306.1 patch bundle for HP-UX 11i v1, Jun 2003
• PHKL_34738 signal cumulative patch, Sep 2006
• PHKL_34173 select(2) delay, hang, Jan 2006
• PHKL_28122 signals, threads enhancement, psets enablement, Feb 2003
• PHNE_36576 cumulative STREAMS patch, Apr 2008
• PHNE_38678 cumulative ARPA transport patch, Apr 2009

Install also these (currently) latest HP-recommended patches for libc, pthread and ld(1) and linker tools:
• PHCO_33282 pthread library cumulative patch, Oct 2006
• PHCO_35743 libc cumulative patch, Jan 2007
• PHSS_37516 ld(1) and linker tools cumulative patch, Dec 2007

For X11 forwarding, install also the following patches on the server machine you want to forward X11:
• PHSS_34102 XClients patch, Dec 2005
• PHSS_35711 X/Motif Runtime Periodic patch, Dec 2006

• HP-UX 11i v2 on PA-RISC and IA-64 (Itanium):
  • B.11.23.0409.3 patch bundle for HP-UX 11i v2, Sep 2004
  • PHCO_34191 libc cumulative patch, Mar 2003
  • PHCO_36323 pthread library cumulative patch, Aug 2007
  • PHSS_37492 linker + fdp cumulative patch, Dec 2007
  • Kerberos Client D.1.6.2, Dec 2007
  • PHNE_34788 cumulative STREAMS patch, May 2007
  • PHNE_37395 cumulative ARPA transport patch, Dec 2007

For X11 forwarding, install also the following patches on the server machine you want to forward X11:
• PHSS_34159 XClients patch, Feb 2006
• PHSS_35046 XMotif Runtime patch, Oct 2006

• HP-UX 11i v3 on PA-RISC and IA-64 (Itanium):
  • PHCO_36551 pthread library cumulative patch, May 2007
  • PHSS_37202 linker and fdp cumulative patch, Oct 2007
  • Kerberos Client D.1.6.2, Dec 2007
2.1.2 Hardware and Disk Space Requirements

Tectia Client does not have any special hardware requirements. Any computer capable of running a current version of the listed operating systems, and equipped with a functional network connection can be used.

The Tectia Client installation requires about 100 megabytes of disk space.

Note that Tectia Client will save each user's settings in that particular user's personal directory.

2.1.3 Licensing

Tectia Client requires a license to function. The license file is named \texttt{stc64.dat}.

Depending on the platform for which you have purchased Tectia Client, consider the following license-related issues:

- In the online installation packages, the license files are included in the compressed (\texttt{.zip/\texttt{.tar}}) files together with the release notes (\texttt{.txt}) files and the PDF-format documentation.

- The Tectia evaluation packages do not contain license files; the evaluation versions can be used for 45 days without a license file. On Unix and Windows machines, a banner message will remind users of how many days are left until the license expires.

2.1.4 Installation Packages

The installation packages of Tectia Client are compressed into installation bundles. There are two bundles for each supported operating system, the commercial version (\texttt{\textasciitilde comm}) and the upgrade and evaluation version (\texttt{\textasciitilde upgrd-eval}). The evaluation versions can be used as upgrade packages, if you already have a suitable license.

Select the relevant Tectia Client bundle:

- For AIX platforms:

  \texttt{tectia-client-<version>-aix-6-7-powerpc-comm.tar}
  \texttt{tectia-client-<version>-aix-6-7-powerpc-upgrd-eval.tar}

- For HP-UX PA-RISC platforms:

  \texttt{tectia-client-<version>-hpux-11i-hppa-comm.tar}
  \texttt{tectia-client-<version>-hpux-11i-hppa-upgrd-eval.tar}

- For HP-UX Itanium platforms:

  \texttt{tectia-client-<version>-hpux-11i-ia64-comm.tar}
  \texttt{tectia-client-<version>-hpux-11i-ia64-upgrd-eval.tar}

- For Linux 32-bit platforms:

  \texttt{tectia-client-<version>-linux-x86-comm.tar}
  \texttt{tectia-client-<version>-linux-x86-upgrd-eval.tar}
• For Linux 64-bit platforms:

```
tectia-client-<version>-linux-x86_64-comm.tar
tectia-client-<version>-linux-x86_64-upgrd-eval.tar
```

• For Solaris SPARC platforms (note the separate packages for Solaris 10 and 11):

```
tectia-client-<version>-solaris-10-sparc-comm.tar
tectia-client-<version>-solaris-10-sparc-upgrd-eval.tar
tectia-client-<version>-solaris-11-sparc-comm.tar
tectia-client-<version>-solaris-11-sparc-upgrd-eval.tar
```

• For Solaris x86-64 platforms (note the separate packages for Solaris 10 and 11):

```
tectia-client-<version>-solaris-10-x86_64-comm.tar
tectia-client-<version>-solaris-10-x86_64-upgrd-eval.tar
tectia-client-<version>-solaris-11-x86_64-comm.tar
tectia-client-<version>-solaris-11-x86_64-upgrd-eval.tar
```

• For Windows platforms:

```
tectia-client-<version>-windows-comm.zip
tectia-client-<version>-windows-upgrd-eval.zip
```

<version> indicates the product release and the current build number (for example 6.4.99.123).

Inside the installation bundles are the actual installation packages for Tectia Client. Select the packages to install according to which product features are relevant in your environment.

On Unix and Linux platforms, the Tectia Client comes in three installation packages:

• the ssh-tectia-common package contains the common components of Tectia Client and Server.

• the ssh-tectia-client package contains the specific components of Tectia Client.

• the optional ssh-tectia-guisupport package contains the components required for the GUI available on Linux platforms.

On Windows, Tectia Client comes in a single MSI installation package, and the installation wizard guides you to select which components to install.

## 2.1.5 Upgrading Previously Installed Tectia Client Software

### Note

Before starting the upgrade, make backups of all configuration files where you have made modifications. See instructions in Section A.3.

If you are running both Tectia Client and Tectia Server on the same machine, install the same release of each Tectia product, because there are dependencies between the common components.

Check if you have some Secure Shell software, for example earlier versions of Tectia products or OpenSSH server or client, running on the machine where you are planning to install the new Tectia versions.
Before installing Tectia Server on Unix platforms, stop any OpenSSH servers running on port 22, or change their listener port. You do not need to uninstall the OpenSSH software.

The following table shows you which Tectia versions you need to uninstall before you can upgrade to Tectia Client 6.4. When upgrading versions marked upgrade on top, the earlier version is automatically removed during the upgrade procedure.

Table 2.2. Upgrade lines

<table>

<td>upgrade on top or remove if Transparent TCP Tunneling is installed</td>
</tr>
</tbody>
</table>

The configuration file format and file locations have been changed in Tectia Client 5.0. Because of that, the configuration files behave differently when upgrading from 4.x and from 5.x-6.x:

- The 4.x configuration files are not migrated to 6.4, but the default 6.4 configuration is used. However, the connection profiles are migrated from 4.x to 6.4 on Windows platforms.

- The 5.x-6.x configuration files are migrated to 6.4 as such and automatically taken into use there.

When necessary, you can modify the configuration files by using the Tectia Connections Configuration GUI or by editing the XML configuration files manually with an ASCII text editor or an XML editor.

If you have the Transparent TCP Tunneling option installed, uninstall the previous version of the client before upgrading to the 6.4 Tectia Client and restart the computer after the uninstallation. See Section 2.3.5.

Note

As of version 6.2.5 of Tectia Client on Windows and 6.4.18 on Unix, the Transparent TCP Tunneling option is no longer included in the installation package.

On Windows, a backup copy is automatically made of the earlier Tectia Client configuration files and stored in the user-specific directory:

"%APPDATA%\SSH\backup-<version>-<date>"

where <version> is the Tectia release and <date> is the date of the upgrade.

2.1.6 Downloading Tectia Releases

All releases require a commercial license that is delivered with the installation package.
To download Tectia software from the SSH Customer Download Center:

1. Log in to the Customer Download Center at: https://my.ssh.com

2. Select Tectia Client from the navigator list, and choose the relevant version. Tectia products are published in major, minor, and maintenance releases:
   - Major releases are indicated with full numbers, for example 6. Major releases publish new products and new major features to existing products, in addition to fixes to the previous versions.
   - Minor releases are indicated with the second digit in the release numbers, for example 6.4. Minor releases publish new features and fixes to the previous versions.
   - Maintenance releases are third digit versions, for example 6.4.99. Maintenance releases provide fixes to the previous versions, not new functionality. The maintenance releases are available for customers with Maintenance and Support Agreement.

3. Click the link with the correct product version and platform, and the compressed installation package will be downloaded to the default download folder on your machine.

4. Proceed to the installation. See the platform-specific installation instructions for Tectia Client below.

**2.2 Installing the Tectia Client Software**

This section gives instructions on installing Tectia Client locally on the supported operating systems.

See the installation instructions for Tectia Client per platform in the following sections.

**2.2.1 Installing on AIX**

The downloaded installation package contains the compressed installation files.

Two packages are required: one for the common components of Tectia Client and Server, and one for the specific components of Tectia Client.

To install Tectia Client on AIX, follow the instructions below:

1. Unpack the downloaded tar package.

2. Unpack the installation packages:

   ```bash
   $ uncompress ssh-tectia-common-<version>-aix-6-7-powerpc.bff.Z
   $ uncompress ssh-tectia-client-<version>-aix-6-7-powerpc.bff.Z
   ```

   In the commands, `<version>` is the current package version of Tectia Client (for example, 6.4.99.123).

3. Install the packages by running the following commands with root privileges:

   ```bash
   # installp -d ssh-tectia-common-<version>-aix-6-7-powerpc.bff SSHTectia.Common
   # installp -d ssh-tectia-client-<version>-aix-6-7-powerpc.bff SSHTectia.Client
   ```
4. Copy the license file to directory: `/etc/ssh2/licenses`. *(This is not necessary in "third-digit" maintenance updates.)* See also Section 2.1.3.

### 2.2.2 Installing on HP-UX

Check that you have the operating system fully patched. See the latest patch information on the Hewlett-Packard web site. In case PAM/Kerberos is used on a HP-UX platform, install also the latest patches related to Kerberos.

The downloaded installation package contains the compressed installation files.

Two packages are required: one for the common components of Tectia Client and Server, and one for the specific components of Tectia Client.

To install Tectia Client on HP-UX, follow the instructions below:

1. Unpack the downloaded `tar` package.

2. Select the installation package according to your HP-UX version.

   When installing on HP-UX 11i v1 (11.11), 11i v2 (11.23), or 11i v3 (11.31) running on the PA-RISC architecture, use the packages named:

   ```
   ssh-tectia-common-<version>-hpux-11i-hppa.depot.Z
   ssh-tectia-client-<version>-hpux-11i-hppa.depot.Z
   ```

   When installing on HP-UX 11i v2 or 11i v3 running on the Itanium architecture, use the packages named:

   ```
   ssh-tectia-common-<version>-hpux-11i-ia64.depot.Z
   ssh-tectia-client-<version>-hpux-11i-ia64.depot.Z
   ```

   In the commands, `<version>` indicates the product release version and the current build number (for example, 6.4.99.123).

3. Unpack the packages with `uncompress`. In order to be installable, the created packages must have the correct long file name. In the command examples below, we use the Itanium versions:

   ```
   $ uncompress ssh-tectia-common-<version>-hpux-11i-ia64.depot.Z
   $ uncompress ssh-tectia-client-<version>-hpux-11i-ia64.depot.Z
   ```

4. Install the packages by running the following commands with root privileges:

   ```
   # swinstall -s <path>/ssh-tectia-common-<version>-hpux-11i-ia64.depot SSHG3common
   # swinstall -s <path>/ssh-tectia-client-<version>-hpux-11i-ia64.depot SSHG3client
   ```

   **Note**

   In the commands, `<path>` is the full path to the installation package. HP-UX requires the full path even when the command is run in the same directory.

5. Copy the license file to directory: `/etc/ssh2/licenses` *(This is not necessary in "third-digit" maintenance updates.)* See Section 2.1.3.
2.2.3 Installing on Linux

Tectia Client for Linux platforms is supplied in RPM (Red Hat Package Manager) binary packages for Red Hat Enterprise Linux and SUSE Linux. There are separate packages for Linux versions running on the 32-bit x86 and the 64-bit x86-64 platform architecture.

The downloaded installation package contains the RPM installation files. Two packages are always required: one for the common components of Tectia Client and Server, and one for the specific components of Tectia Client. If you want to use the product with a graphical user interface (GUI), install also the optional GUI support package.

To install Tectia Client on Linux, follow the instructions below:

1. If installing on RHEL 8, install prerequisite packages:

   ```bash
   # yum install ncurses-compat-libs
   ```

2. Unpack the downloaded `tar` package.

3. Select the installation package according to your Linux architecture.

   When installing on SUSE or Red Hat Enterprise Linux running on the 32-bit x86 architecture, use the packages named:

   ```
   ssh-tectia-common-<version>-linux-x86.rpm
   ssh-tectia-client-<version>-linux-x86.rpm
   ssh-tectia-guisupport-<version>-linux-x86.rpm
   ```

   When installing on SUSE or Red Hat Enterprise Linux versions running on the 64-bit x86-64 architecture, use the packages named:

   ```
   ssh-tectia-common-<version>-linux-x86_64.rpm
   ssh-tectia-client-<version>-linux-x86_64.rpm
   ssh-tectia-guisupport-<version>-linux-x86_64.rpm
   ```

   In the commands, `<version>` indicates the product release version and the current build number (for example, 6.4.99.123).

4. Install the packages with root privileges. In the command examples below, we use the x86-64 version:

   ```
   # rpm -Uvh ssh-tectia-common-<version>-linux-x86_64.rpm
   # rpm -Uvh ssh-tectia-client-<version>-linux-x86_64.rpm
   # rpm -Uvh ssh-tectia-guisupport-<version>-linux-x86_64.rpm
   ```

5. Copy the license file to the `/etc/ssh2/licenses` directory. *(This is not necessary in "third-digit" maintenance updates.)* See also Section 2.1.3.

2.2.4 Installing on Solaris

The downloaded installation package contains the compressed installation files.

Two packages are required: one for the common components of Tectia Client and Server, and one for the specific components of Tectia Client.
Tectia Client includes support for Zones on Solaris 10 and 11. The Tectia software can be installed into the global and local zones. When the Tectia software is installed into the global zone, it becomes automatically installed also into the existing local zones. However, if the local zones are added into the system later, the Tectia Client needs to be separately installed on them.

In case you are installing Tectia Client into a sparse zone, note that the installation process will report a failure in creating symlinks. The actual installation is finished successfully, but you need to manually add the /opt/tectia/bin to the path settings.

For information on the Solaris Zones, see the Oracle documentation: System Administration Guide: Solaris Containers-Resource Management and Solaris Zones.

To install Tectia Client on Solaris, follow the instructions below:

1. Unpack the downloaded tar package.
2. Select the installation package according to your Solaris version.

   When installing on Solaris version 10 running on the SPARC architecture, use the packages named:

   - ssh-tectia-common-<version>-solaris-10-sparc.pkg.Z
   - ssh-tectia-client-<version>-solaris-10-sparc.pkg.Z

   When installing on Solaris version 11 running on the SPARC architecture, use the packages named:

   - ssh-tectia-common-<version>-solaris-11-sparc.pkg.Z

   When installing on Solaris version 10 or 11 running on the x86-64 architecture, use the packages named:

   - ssh-tectia-common-<version>-solaris-<solaris-version>-x86_64.pkg.Z
   - ssh-tectia-client-<version>-solaris-<solaris-version>-x86_64.pkg.Z

   In the commands, <version> indicates the product release version and the current build number (for example, 6.4.99.123). <solaris-version> refers to the Solaris version number (10 or 11), in case of installing on x86-64 architecture.

3. Unpack the installation packages to a suitable place. The standard place is /var/spool/pkg in Solaris environment. In the command examples below, we use Solaris 10 x86-64:

   $ uncompress ssh-tectia-common-<version>-solaris-10-x86_64.pkg.Z
   $ uncompress ssh-tectia-client-<version>-solaris-10-x86_64.pkg.Z

4. Install the packages with the pkgadd tool with root privileges:

   # pkgadd -d ssh-tectia-common-<version>-solaris-10-x86_64.pkg all
   # pkgadd -d ssh-tectia-client-<version>-solaris-10-x86_64.pkg all

5. Copy the license file to directory: /etc/ssh2/licenses (This is not necessary in "third-digit" maintenance updates.) See also Section 2.1.3.

### 2.2.5 Installing on Windows
The Windows installation packages are provided in the MSI (Windows Installer) format. There are separate Tectia Client installation packages for Microsoft Windows versions running on the 32-bit (x86) and 64-bit (x86-64) platform architectures.

The downloaded installation package is a zip file containing the license file and the executable Windows Installer (MSI) packages.

The installation is carried out by a standard installation wizard. The wizard prompts you for information, copies the program files, and sets up the client.

**Note**

If you want to install both Tectia Client and Tectia Server on the same machine, you must install both products using the Tectia Server installer `ssh-tectia-server-<version>-windows-<platform>.msi`, where `<version>` shows the Tectia Client/Server release version and build number (for example 6.4.99.123), and `<platform>` shows the platform architecture (x86 for 32-bit and x86_64 for 64-bit Windows versions).

If you are upgrading a previous installation of Tectia Client, see first Section 2.1.5.

To install Tectia Client on Windows, follow the instructions below:

1. Extract the installation zip file contents to a temporary location.

2. Locate the correct Windows Installer file `ssh-tectia-client-<version>-windows-<platform>.msi`, where:
   - `<version>` shows the Tectia Client/Server release version and build number, for example 6.4.99.123.
   - `<platform>` shows the platform architecture: x86 for 32-bit and x86_64 for 64-bit Windows versions.

3. Double-click the installation file, and the installation wizard will start.

**Note**

The license file will be imported automatically, when you extract the contents of the .zip package before running the .msi installer.

If you run the .msi installer directly from the .zip package, you need to manually import the stc64.dat license file after completing the installation. The installation wizard will show an error message about missing license file (see below), and when you attempt to start the Tectia Client, you are prompted to import the license manually to the correct directory:

- "C:\Program Files\SSH Communications Security\SSH Tectia\SSH Tectia AUX\licenses" on 32-bit Windows versions
- "C:\Program Files (x86)\SSH Communications Security\SSH Tectia\SSH Tectia AUX\licenses" on 64-bit Windows versions
4. Follow the wizard through the installation steps and fill in information as requested.

5. The **Typical** installation of Tectia Client includes the `sshg3.exe`, `scpg3.exe`, and `sftpg3.exe` command-line tools, and the graphical user interface for terminal and file transfer.

   To install all components, select **Complete** when the wizard prompts for the setup type.

   If you want to select the components to install, select **Custom** when the wizard prompts for the setup type. The next dialog box allows you to exclude some of the components from the installation. See **Figure 2.2**.

---

**Figure 2.1. Warning about a missing license file**

On Windows 10, Tectia packages downloaded via browser may trigger a *Windows protected your PC* warning. In such cases, proceed with the installation by clicking **More info** and **Run anyway**.

---

**Figure 2.2. Installation options with Tectia Client**
6. When the installation has finished, click **Finish** to exit the wizard.

7. You have to restart the computer after installing Tectia Client. Click **Yes** to restart.

The default installation directory is:

- "C:\Program Files\SSH Communications Security\SSH Tectia" on 32-bit Windows versions
- "C:\Program Files (x86)\SSH Communications Security\SSH Tectia" on 64-bit Windows versions

**Silent Installation**

Tectia Client can also be installed silently on a workstation. Silent (non-interactive) installation means that the installation procedure will not display any user interface and will not ask any questions from the user. This option is especially useful for system administrators, as it allows remotely-operated automated installations.

In silent mode, Tectia Client is installed with the default settings and without any additional features.

The following command can be used to install Tectia Client silently:

```
msiexec /q /i ssh-tectia-client-<version>-windows-<platform>.msi INSTALLDIR="<path>"
```

In the command:

- `<version>` shows the current version of Tectia Client, for example 6.4.99.123.
- `<platform>` shows the platform architecture: x86 for 32-bit and x86_64 for 64-bit Windows versions.
- `<path>` is the path to the desired installation directory. If the INSTALLDIR variable is omitted, Tectia Client is installed to the default location.

**Desktop Icons**

During installation, Tectia icons are added to your desktop. There are separate program icons for Tectia SSH Terminal and Secure File Transfer windows. They both start the same application, `ssh-client-g3.exe`. The first icon starts the terminal window and the latter starts the file transfer window.

![Tectia SSH Terminal GUI icon](image)

**Figure 2.3. The Tectia SSH Terminal GUI icon**
2.3 Removing the Tectia Client Software

This section gives instructions on removing Tectia Client from the supported operating systems.

**Note**

The uninstallation procedure removes only the files that were created when installing the software. Any configuration files have to be removed manually.

### 2.3.1 Removing from AIX

To remove Tectia Client from an AIX environment, follow the instructions below:

1. Remove the installation by issuing the following command with root privileges:

   ```bash
   # installp -u SSHTectia.Client
   ```

2. If you want to remove also the components that are common with Tectia Server, give the following command:

   ```bash
   # installp -u SSHTectia.Common
   ```

   Note that removing the common components disables Tectia Server, if it has been installed on the same host.

### 2.3.2 Removing from HP-UX

To remove Tectia Client from an HP-UX environment, follow the instructions below:

1. Remove the installation by issuing the following command with root privileges:

   ```bash
   # swremove SSHG3client
   ```

2. If you want to remove also the components that are common with Tectia Server, give the following command:

   ```bash
   # swremove SSHG3common
   ```

   Note that removing the common components disables Tectia Server, if it has been installed on the same host.

### 2.3.3 Removing from Linux
To remove Tectia Client from a Linux environment, follow the instructions below:

1. Remove the installation by issuing the following command with root privileges:

   ```
   # rpm -e ssh-tectia-client-<version>
   ```

   In the command, `<version>` is the package version of Tectia Client to be removed (for example, 6.4.99-123).

2. If you want to remove also the components that are common with Tectia Server, give the following command:

   ```
   # rpm -e ssh-tectia-common-<version>
   ```

   Note that removing the common components disables Tectia Server, if it has been installed on the same host.

3. To remove the GUI components, issue the following command with root privileges:

   ```
   # rpm -e ssh-tectia-guisupport-<version>
   ```

### 2.3.4 Removing from Solaris

To remove Tectia Client from a Solaris environment, follow the instructions below:

1. Remove the installation by issuing the following command with root privileges:

   ```
   # pkgrm SSHG3clnt
   ```

2. If you want to remove also the components that are common with Tectia Server, give the following command:

   ```
   # pkgrm SSHG3cmmn
   ```

   Note that removing the common components disables Tectia Server, if it has been installed on the same host.

### 2.3.5 Removing from Windows

There are several ways to remove the Tectia Client installation from Windows. Follow one set of instructions below:

#### Using Windows Control Panel tools

1. From the Windows Start menu, open the Control Panel and click Programs and Features.

2. Select Tectia Client from the list of installed programs and click Uninstall.

3. Click Yes to confirm.

#### Using the Windows Installer

1. Locate the Windows Installer file ssh-tectia-client-<version>-windows-<platform>.msi, where:
• <version> shows the Tectia Client/Server release version and build number, for example 6.4.99.123.

• <platform> shows the platform architecture: x86 for 32-bit and x86_64 for 64-bit Windows versions.

On some Windows versions the .msi file type is not shown for the installer file.

2. Double-click the installer file, and the Windows Installer will start.

3. Select Remove to start the uninstallation.

4. Click Finish when the removal has been completed.

Using Silent Command-line Tools

Tectia Client can also be removed silently by giving the following command:

msiexec /q /x ssh-tectia-client-<version>-windows-<platform>.msi

In the command, <version> is the version of Tectia Client to be removed (for example, 6.4.99.123), and <platform> shows the platform architecture (x86 for 32-bit and x86_64 for 64-bit Windows versions).

2.4 Files Related to Tectia Client

This section lists the default locations where the installation process will store the Tectia Client executables, configuration files, the license file, and the user-specific configuration files.

2.4.1 File Locations on Unix

On Unix platforms, the Tectia Client files are located in the following directories:

• /etc/ssh2
  • /etc/ssh2/ssh-broker-config.xml: the global Connection Broker configuration file (see ssh-broker-config(5))
  • /etc/ssh2/ssh-broker-config-example.xml: a sample file with Connection Broker configuration examples
  • /etc/ssh2/licenses: the license file directory (see Section 2.1.3).
  • /etc/ssh2/hostkeys: the global directory for known remote host keys
  • /opt/tectia/share/auxdata/ssh-broker-ng: the Connection Broker configuration file DTD directory
  • /opt/tectia/share/auxdata/ssh-broker-ng/ssh-broker-ng-config-1.dtd: the document type definition (DTD) used with the Connection Broker configuration files. Do not edit this file!
• /opt/tectia/share/auxdata/ssh-broker-ng/ssh-broker-config-default.xml: this configuration file is read first, and it holds the factory default settings. **Do not edit** this file, but you can use it to view the default settings. This file must be available and correctly formatted for the Connection Broker to start. For the configuration options, see ssh-broker-config(5).

**Note**

In Tectia Client 6.1 and earlier on Unix the default auxiliary data directory **auxdata** was located in /etc/ssh2/ssh-tectia/. If your ssh-broker-config.xml file was created for Tectia Client version 6.1 or earlier, please update its DOCTYPE declaration to contain the current path to the Connection Broker configuration file DTD directory: /opt/tectia/share/auxdata/ssh-broker-ng/.

• /opt/tectia/bin: user binaries such as sshg3 and ssh-broker-g3

• /opt/tectia/man: the manual pages

• /opt/tectia/libexec: library binaries

• /opt/tectia/lib/sshsecsh: library binaries

The user-specific configurations are stored in the following directories:

• $HOME/.ssh2/ssh-broker-config.xml: the user-specific Connection Broker configuration file

• $HOME/.ssh2: the default directory for user keys

• $HOME/.ssh2/random_seed: the seed file for the random number generator

• $HOME/.ssh2/hostkeys: the user-specific directory for known remote host keys

• $HOME/.ssh2/identification: *(optional)* the identification file used with public-key authentication

### 2.4.2 File Locations on Windows

On Windows, the default installation directory (<INSTALLDIR> below) for Tectia products is:

• "C:\Program Files\SSH Communications Security\SSH Tectia" on 32-bit Windows versions

• "C:\Program Files (x86)\SSH Communications Security\SSH Tectia" on 64-bit Windows versions

On Windows, the Tectia Client files are located in the following directories:

• "<INSTALLDIR>\SSH Tectia Client": the binaries for Tectia Client

• "<INSTALLDIR>\SSH Tectia Broker": the Connection Broker binaries and example configuration files
• "<INSTALLDIR>\SSH Tectia Broker\ssh-broker-config.xml": the global Connection Broker configuration file (see its manpage: ssh-broker-config(5))

• "<INSTALLDIR>\SSH Tectia Broker\ssh-broker-config-example.xml": a sample file with Connection Broker configuration examples

• "<INSTALLDIR>\SSH Tectia AUX": auxiliary files and binaries such as ssh-keygen-g3.exe

• "<INSTALLDIR>\SSH Tectia AUX\ssh-broker-ng": the Connection Broker configuration file DTD directory

• "<INSTALLDIR>\SSH Tectia AUX\ssh-broker-ng\ssh-broker-config-default.xml": this configuration file is read first and it holds the factory default settings. Do not edit this file, but you can use it to view the default settings. This file must be available and correctly formatted for the Connection Broker to get started. For the configuration options, see ssh-broker-config(5).

• "<INSTALLDIR>\SSH Tectia AUX\ssh-broker-ng\ssh-broker-ng-config-1.dtd": the document type definition (DTD) used with the Connection Broker configuration files. Do not edit this file!

• "<INSTALLDIR>\SSH Tectia AUX\licenses": the license file directory (see Section 2.1.3)

• "<INSTALLDIR>\SSH Tectia AUX\documents": the end-user license agreements.

• "C:\Documents and Settings\All Users\Application Data\SSH\hostkeys": the global directory for known host keys (on pre-Vista Windows).

• "C:\ProgramData\SSH\hostkeys": the global directory for known host keys (on Windows Vista and later Windows versions).

Figure 2.5 shows the Tectia directory structure in the Windows Start menu when several Tectia products have been installed on the same machine.

![Tectia directory structure on Windows](image)

**Figure 2.5. The Tectia directory structure on Windows**

The user-specific configurations are stored in the directories as listed below.
• %APPDATA%\SSH\ssh-broker-config.xml: the user-specific Connection Broker configuration file

• %APPDATA%\SSH\global.dat: the Tectia SSH Terminal GUI configuration file

• %APPDATA%\SSH\*.ssh2: the Tectia SSH Terminal GUI profile configuration files

• %APPDATA%\SSH\random_seed: the seed file for the random number generator

• %APPDATA%\SSH\HostKeys: the user-specific directory for known remote host keys

• %APPDATA%\SSH\UserKeys: the default directory for user public-key pairs

• %APPDATA%\SSH\UserCertificates: the default directory for user certificate key pairs

• %APPDATA%\SSH\identification: (optional) the identification file used with public-key authentication

**Note**

The user-specific %APPDATA% directory is hidden by default. To view hidden directories, change the setting in Windows Explorer. For example, on Windows 7, select Organize → Folder and search options on the menu. On the View tab, under Hidden files and folders, select Show hidden files, folders and drives.

### 2.4.3 Registry Keys on Windows

On Windows, the Tectia Client installation creates the following registry keys:

• HKLM\SYSTEM\CurrentControlSet\Services\EventLog\Application\SSH Tectia Broker

• HKLM\SYSTEM\CurrentControlSet\Services\EventLog\Application\SSH Tectia Broker GUI

• HKLM\SOFTWARE\SSH Communications Security\SSH Tectia

• HKLM\SOFTWARE\SSH Communications Security\SSH Tectia Client

• HKLM\SOFTWARE\Wow6432Node\SSH Communications Security\SSH Tectia (on x64 architecture, only)

• HKLM\SOFTWARE\Wow6432Node\SSH Communications Security\SSH Tectia Client (on x64 architecture, only)

### 2.5 Symlinks between ssh/scp/sftp and sshg3/scpg3/sftpg3 (on Unix)

By default, Tectia Client does not create symlinks between the command-line clients sshg3, scpg3 and sftpg3, and their earlier versions ssh, scp and sftp.
In case you want to make sure that the \texttt{sshg3/scpg3/sftpg3} clients are always used instead of the \texttt{ssh/scp/sftp} clients (even when the user types in \texttt{ssh/scp/sftp}) make symlinks between them by running the following script any time after the installation:

```
# /opt/tectia/libexec/ssh-create-4.x-compat-symlinks
```

The symlink is needed as the two versions of the clients are located in different directories:

\texttt{sshg3/scpg3/sftpg3}

\begin{itemize}
\item \texttt{sshg3/scpg3/sftpg3} are located in \texttt{/opt/tectia/bin/sshg3}
\end{itemize}

\texttt{ssh/scp/sftp}

\begin{itemize}
\item \texttt{ssh/scp/sftp} are located in \texttt{/usr/local/bin/ssh}
\end{itemize}
Chapter 3 Getting Started with Tectia Client

This chapter provides information on how to get started with Tectia Client software after it has been successfully installed.

3.1 Product Components

Tectia Client consists of the following components:

- The Connection Broker: `ssh-broker-g3, ssh-broker-ctl`
- Secure Shell command-line tools: `sshg3, scpg3, sftpg3`
- Auxiliary command-line tools: `ssh-keygen-g3, ssh-cmpclient-g3, ssh-scepclient-g3, ssh-certview-g3, ssh-ekview-g3`
- Tectia SSH Terminal GUI (Windows) (see Section 3.2.1)
- Tectia Secure File Transfer GUI (Windows) (see Section 5.2)
- Tectia Connections Status GUI on Linux and Windows platforms (see Section A.6.1)
- Tectia Connections Configuration GUI on Linux and Windows platforms (see Section A.1)

3.2 First Login to a Remote Host

This section gives basic instructions on how you can log in from Tectia Client to a Secure Shell server with the default settings. The default settings on Tectia Client and Tectia Server allow login with passwords, public keys, and GSSAPI.

There are separate instructions on using the Tectia SSH Terminal GUI on Windows to connect to a remote server host (see Section 3.2.1) and on using `sshg3` on the command line on Windows and Unix (see Section 3.2.2).
Tectia Client includes a shortcut menu that helps configuring the connection settings, and in viewing the status of the connections and authentication keys. For a description of the Tectia shortcut menu, see Section A.6.

### 3.2.1 Logging in with Tectia SSH Terminal GUI (on Windows)

With Tectia Client it is easy to establish connections to new remote host computers, and to manage the settings required for each host. The Quick Connect option allows you to quickly open new connections, minimizing the work associated with configuring each connection. It is easy to define profiles for new hosts, and save the correct settings for each.

On Windows, you can connect to a remote host by using the Tectia SSH Terminal GUI as follows:

1. Open the Tectia SSH Terminal by clicking its icon on your desktop:

   ![Figure 3.1. The Tectia SSH Terminal icon](image)

2. Tectia SSH Terminal GUI offers several ways to open a Secure Shell connection:

   - If you already have a session open, click the **Quick Connect** command (toolbar or **File** menu). You can connect to a new remote host computer and still keep the old connection to a different host open.

   - If you have closed an earlier session, you can open a new session by pressing **Enter** or **Space** on the keyboard when the (still disconnected) terminal window is active.

     - **Enter** connects you directly to the same remote server as the previous session.

     - **Space** opens the **Connect to Server** dialog box, and you can define the server where you wish to connect.

   - If you have defined connection profiles, you can also connect by clicking **File → Profiles → **<Profilename>** on the menu, or clicking the **Profiles** button on the toolbar and clicking the profile name.

     In this case, the settings defined in the profile (hostname, port, user name etc.) are automatically used for the connection and the **Connect to Server** dialog box is not shown. For instructions on creating and editing the connection profiles, see Section A.1.3.

3. The server authentication phase starts. The remote server host will provide your local computer with its host public key. The host key identifies the server host.
Tectia Client checks if information on this key is already stored in your own host key directory. If not, the host key directory common to all users on your computer is checked next. If information on this host key is not found, you are asked to verify the new key.

When public-key authentication is used to authenticate the server, the first connection is very important. When Tectia Client receives a new server host key, it will display the host identification message.

Figure 3.3. The host identification dialog – the first connection to a remote host

The message displays the fingerprint of the host’s public key in the SSH Babble format that is a series of pronounceable five-letter words in lower case and separated by dashes.

5. Verify the validity of the fingerprint, preferably by contacting the administrator of the remote host computer by telephone. After verifying the fingerprint, it is safe to save information on the host key for future use. You can also choose to cancel the connection, or to proceed with this connection without saving the host public key information.

Caution

Never save a host public key without verifying its authenticity!

6. Click OK to close the host identification dialog.

Information on the server public key will be stored on the client-side machine so that the client can later validate the key. On Tectia Client, the public key information is stored in the "%APPDATA%\SSH\HostKeys” directory.

• "C:\Documents and Settings\<username>\Application Data” on pre-Vista Windows versions

• "C:\Users\<username>\AppData\Roaming" on Windows Vista and later

After the first connection, only the locally stored information about the server public key will be used in server authentication.
For more information on server authentication, see Section 4.2.

7. The user authentication phase starts. You will be prompted to authenticate yourself to the server using the authentication method you selected in the Connect to Server dialog, or by default with your password or with the passphrase of your private key. The required authentication method depends on the server settings.

After the server has successfully authenticated you, the Secure Shell connection to the server is opened.

8. (Optional) If you did not use a connection profile when connecting, an Add Profile dialog box appears for 5 seconds, allowing you to create a new connection profile with the information you provided for the connection. In the Profile Name field, type in a name for the new profile. Then click Add to Profiles. The Tectia Connections Configuration GUI opens, showing the information for the new profile. Click Apply to save the new connection profile. For detailed instructions on editing the connection profile, see Section A.1.3.

3.2.2 Logging in with Command-Line sshg3

You can connect to a remote host by using sshg3 on the command line:

1. Enter the sshg3 command using the following syntax:

   $ sshg3 <hostname>

   For example:

   $ sshg3 abc.example.com

   The basic syntax is:

   $ sshg3 user@host#port

   where:

   • user - Enter a user name that is valid on the remote host. The user@ attribute is optional. If no user name is given, the local user name is assumed.

   • host - Enter the name of the remote host as an IP address, FQDN (fully qualified domain name), or short host name. The remote host must be running a Secure Shell version 2 server.

   • port - Enter the number of the Secure Shell listen port on the remote server. The #port attribute is optional. If no port is given, the default Secure Shell port 22 is assumed.

If you have defined connection profiles in the ssh-broker-config.xml file, you can also connect by using the name of the connection profile, for example:

   $ sshg3 profile1

   In this case, the settings defined in the profile (host name, port, user name etc.) are used for the connection. For instructions on creating and editing the connection profiles, see the section called “The profiles Element”.

For more information on the `sshg3` commands and options, see `sshg3(1)`.

2. The server authentication phase starts. The server sends its public key to the client for validation (when server public-key authentication is used).

Tectia Client checks if this key is already stored in your own host key directory. If not, the host key directory common to all users on your computer is checked next.

If the host key is not found, you are asked to verify it.

When Tectia Client receives a new host public key, a host identification message is displayed. For example:

```
$ sshg3 user@host
Host key not found from database.
Key fingerprint:
xeic-fifub-kiyh-kohag-zedy-n-pycuz-besug-galoh-gupah-xaxby
You can get a public key's fingerprint by running
% ssh-keygen-g3 -F publickey.pub
on the keyfile.
Are you sure you want to continue connecting (yes/no)?
```

The message shows the fingerprint of the host’s public key in the SSH Babble format that is a series of pronounceable five-letter words in lower case and separated by dashes.

3. Verify the validity of the fingerprint, preferably by contacting the administrator of the remote host computer by telephone.

After the fingerprint has been verified and found to be correct, it is safe to save the key and continue connecting. You can also select to cancel the connection, or to proceed with the connection without saving the key.

If you choose to save the server public key, relevant information about the key will be stored on the client host in directory `$HOME/.ssh2/hostkeys` on Unix or in `%APPDATA%\SSH\HostKeys` on Windows. After the first connection, the locally stored information about the server public key will be used in server authentication.

For more information on server authentication, see Section 4.2.

4. The user authentication phase starts. You will be prompted to authenticate yourself to the server with your password or with the passphrase of your private key (if your public key has already been uploaded to the server). The required authentication method depends on the server settings.

After the server has successfully authenticated you, the Secure Shell connection to the server is opened.

### 3.3 Using Public-Key Authentication

Public-key authentication is based on the use of digital signatures. To use public-key authentication, you must first create a key pair on the client, and upload the public key to the server. For instructions, see Section 4.5.
At connection establishing phase, the server sends Tectia Client a challenge. Sign the challenge with the passphrase of your private key. After the server has successfully completed user authentication, the Secure Shell connection to the server is opened.

The Connection Broker operates automatically as an authentication agent. It offers an easy method for utilizing also digital certificates and smart cards. The authentication forwarding functionality allows the forwarding of public-key authentication over several Secure Shell connections. The Connection Broker is started automatically when you start Tectia Client.

### 3.4 Configuring Tectia Client

Tectia Client includes a default configuration that can get you started. To tailor the Tectia Client behaviour according to the needs of your environment, you can edit the existing configuration.

A component called Connection Broker handles all cryptographic operations and authentication-related tasks for SSH operations of Tectia Client, so all the related settings are made in the Connection Broker configuration.

On Linux and Windows, Tectia Client provides a graphical user interface for handling the Connection Broker configuration. On other platforms, the configuration can be edited directly in the configuration file (in XML format). The Connection Broker settings can be edited using the Tectia Connections Configuration GUI that is available behind the icon in the Status bar and in the Tectia SSH Terminal GUI.

On Windows, you can - optionally - modify the layout, colors and behaviour of the Tectia SSH Terminal GUI and Tectia Secure File Transfer GUI according to your taste with the User Interface Settings tool (available behind the icon in the tool bar of Tectia SSH Terminal GUI). For instructions on configuring the user interface layout, see Appendix B.

### 3.4.1 Connection Broker Configuration

For users of Tectia Client, the most relevant and most typically needed item to configure for the Connection Broker are the connection profile settings. All other settings are typically configured by system administrators.

It is advisable to create connection profiles for servers where you will need to connect repeatedly. The profiles contain the server ID, your user name on that server, and information on the authentication method to be used.

In general, the following aspects can be configured for the Connection Broker:

**Secure connection details**

These settings define how Tectia Client will establish the secure connections to the remote servers, for example: what type of a connection will be opened, what authentication methods will be applied, will a proxy be used and is tunneling allowed.
User and server authentication methods

The user authentication settings define the methods Tectia Client will use when sending user authentication data to the remote servers. The Tectia Connections Configuration GUI includes a public-key wizard (on Linux and Windows) that helps in creating and uploading public keys to the servers.

The server authentication settings define how the remote servers will be authenticated by Tectia Client.

Tunneling of connections

Tunnels can be defined to secure all or some TCP applications and FTP connections. It is also possible to allow forwarding of X11 sessions and SSH connections from one remote server to another.

Tip

The first things to configure are the user authentication settings (creating public keys for the users and uploading them to remote servers) and creating connection profiles for servers where you will need to connect repeatedly.

For instructions on defining the authentication settings, see Chapter 4, and for the authentication-related options in the configuration file, see authentication-methods.

For instructions on creating connection profiles via the GUI, see Section A.1.3, and about adding connection profiles directly into the configuration file, see the section called “The profiles Element”.

For a detailed description of the Connection Broker configuration options, see Appendix A.

3.4.2 Connection Broker Configuration Files

The Connection Broker configuration is stored in an XML file named ssh-broker-config.xml. You can edit the configuration file with your favorite XML or text editor, but make sure ssh-broker-config.xml remains a valid XML file. For details about the Connection Broker configuration options, see ssh-broker-config(5).

When you want to modify the Connection Broker configuration, you will typically edit a user-specific copy of the configuration file stored in $HOME/ .ssh2 on Unix, %APPDATA%\SSH \ on Windows). You need to create the user-specific configuration file first.

The Tectia Connections Configuration GUI on Windows and Linux also writes to the user-specific configuration file automatically.

For a list of the related configuration files and their locations:

- on Unix, refer to Section 2.4.1
- on Windows, refer to Section 2.4.2

3.4.3 Command-Line Tools
Chapter 3 Getting Started with Tectia Client

Tectia Client includes command-line tools sshg3, scpg3 and sftpg3 that can be used to open secure connections and to transfer files securely - the same as with the Tectia SSH Terminal GUI and Tectia Secure File Transfer GUI.

These tools can be used in scripts and in real-time with a set of options detailing their behaviour. The options given on command line will override the settings specified in the configuration file.

The options of each command-line tool are described on the man pages sshg3(1), scpg3(1), and sftpg3(1)).

3.5 Creating Connection Profiles

On Tectia Client on Windows and Linux, you can configure separate connection settings for each Secure Shell server you connect to. You can also create several profiles for the same server, for example, with different user accounts.

On Windows, you can add connection profiles via the following views:

• Start Tectia SSH Terminal GUI and click the Profiles button. Select Add profile from the drop-down menu, as shown in the following figure.

![Figure 3.4. Adding connection profiles](image)

Figure 3.4. Adding connection profiles

• Start Tectia SSH Terminal GUI and open the Tectia Connections Configuration GUI by clicking the Tectia icon on the toolbar.

(Alternatively, you can open the Tectia Connections Configuration GUI by right-clicking the Tectia icon in the Windows taskbar notification area and selecting Configuration from the shortcut menu.)

On Linux, open the Tectia Connections Configuration GUI:

1. Go to the /opt/tectia/bin directory by entering:

   `$ cd /opt/tectia/bin/

2. Start the Tectia Connections Configuration GUI with the following command:
In the Tectia Connections Configuration GUI, go to the **Connection Profiles** page (as shown below) and click **Add profile**.

**Figure 3.5. Adding connection profiles**

Newly created connection profiles will inherit the default values for authentication, ciphers, MACs, KEXs, tunneling, and advanced server settings defined under the **General → Default Connection** page. The values can be customized on the profile-specific tabbed pages, see **Figure 3.6**.

To rename a connection profile, right-click the profile name in the **Connection Profiles** list and click **Rename**. Type in the new name.

To remove a connection profile, select the profile and click **Delete**. You will be asked for confirmation. Click **Yes** to proceed with the deletion.

### 3.5.1 Defining Connection Profile Settings

Under the **Connection Profile** page, on the **Connection** tab, you can define the protocol settings used in the connection. Any changed connection settings will take effect the next time you log in.
Figure 3.6. Configuring connection profiles

Profile

In **Profile name**, type a name for the profile.

Host

In **Host name**, enter the name of the remote host computer to which you want to connect with the profile.

In **Port number**, enter the port number you want to use for the Secure Shell connection. The default port is 22.

**Note**

A Secure Shell server program must be listening to the specified port on the remote host computer or the connection attempt will not succeed. If you are unsure which port the remote host computer is listening to, contact the system administrator of the remote host.
User Name

Select **Use current user name** if the connection should always be made using the currently logged in Windows or Unix user name. This is similar to defining `%USERNAME%` (note the percent signs) as the user name.

Select **Specify user name** and enter the user name, if you want to define the user name to be used when connecting to the remote host computer. If you specify `%USERNAME%` (note the percent signs) as the user name, it will be replaced with the name of the current Windows or Unix user account upon connecting.

Advanced

*Not needed now:* In **Compression**, select the desired compression setting from the drop-down menu. Valid choices are **zlib** and **none**. Compression is disabled by default.

*Not needed now:* In **Tunnel using profile**, select the desired connection profile from the drop-down menu. Any nested tunnels will be created through the profile. For information on the tunneling features, refer to Chapter 6.

### 3.6 Enabling FIPS 140-2 Mode

You can enable Tectia Client to operate in FIPS mode after which all cryptographic operations are run according to the FIPS 140-2 standard.

In FIPS mode, OpenSSL cryptographic library is used for all cryptographic operations, see Section 3.6.3. In Standard mode, Tectia proprietary cryptographic library is used for all cryptographic operations.

**Note**

In FIPS mode, due to a FIPS regulation which forbids exporting unencrypted private keys out of the FIPS module, it is not possible to generate user keys without a passphrase.

#### 3.6.1 Enabling FIPS Mode Using Configuration GUI

To enable FIPS mode on Windows:

1. Open Tectia Connections Configuration GUI (see Section A.1.1).
2. Go to the General settings by selecting **General** in the tree view.
3. Under **Cryptographic Library**, select **FIPS mode**.
4. Ensure that the cryptographic algorithms defined for the default connection settings or any connection profile are compatible with FIPS mode. You are informed of algorithms that are not allowed in FIPS mode. For FIPS-compatible algorithms, see the section called “Defining Ciphers”, the section called “Defining MACs” and the section called “Defining KEXs”.

© 1995–2021 SSH Communications Security

Tectia® Client 6.4 User Manual
5. Click **Apply**.

### 3.6.2 Enabling FIPS Mode Using Configuration File

To enable FIPS mode on Unix:

1. Open the Connection Broker configuration file `ssh-broker-config.xml` that you want to modify (see the section called “Connection Broker Files”).

2. Under the `general` element, modify the `crypto-lib` element by setting its value to `fips`.

3. Ensure that the cryptographic algorithms defined in the configuration file for the `default-settings` element and the `profiles` element are compatible with FIPS mode. For FIPS-compatible algorithms, see `ciphers`, `macs` and `kexs`.

4. Save the configuration file and reload the file to Connection Broker.

### 3.6.3 FIPS-Certified Cryptographic Library

Tectia products can be operated in FIPS mode, using a version of the cryptographic library that has been certified according to the Federal Information Processing Standard (FIPS) 140-2.

The full OpenSSL cryptographic library is distributed with Tectia Client. However, only the algorithms provided by the `fipscanister` object module in the library are used by Tectia Client. The OpenSSL FIPS-certified cryptographic library is used to provide the classes of functions listed in the following tables.

The functions from the OpenSSL library version 1.0.2a used on Linux, Windows, Solaris and HP-UX Itanium (IA-64) are listed in Table 3.1. On these platforms, the `fipscanister` object module version 2.0.9 is used.

The functions from the OpenSSL library version 0.9.8 used on HP-UX PA-RISC and IBM AIX are listed in Table 3.2. On these platforms, the `fipscanister` object module version 1.2 is used.

#### Table 3.1. APIs used from the OpenSSL cryptographic library version 1.0.2a (used on Linux, Windows, Solaris and HP-UX Itanium)

No certificate functions are used from the OpenSSL library. Tectia provides its own certificate libraries.
Chapter 4 Authentication

The Secure Shell protocol used by the Tectia client/server solution provides mutual authentication – the client authenticates the server and the server authenticates the client user. Both parties are assured of the identity of the other party.

The remote Secure Shell server host can authenticate itself using either traditional public-key authentication or certificate authentication.

Different methods can be used to authenticate Secure Shell client users. These authentication methods can be combined or used separately, depending on the level of functionality and security you want.

![User authentication methods](image)

**Figure 4.1. User authentication methods**

User authentication methods used by Tectia Client by default are: public-key, password, keyboard-interactive, and GSSAPI authentication. Public-key and certificate authentication are combined into the public-key authentication method.

When several interactive authentication methods are defined as allowed, Tectia Client will alternate between the methods and offers each of them in turn to the server in case the previous method failed. This makes it possible to define different authentication methods for different users, and they can be handled with the same server configuration.

### 4.1 Supported User Authentication Methods

The following user authentication methods are supported in the Tectia client/server solution.
Table 4.1. User authentication methods supported by the Tectia client/server solution

4.1.1 Compatibility with OpenSSH Keys

By default, the Tectia client/server solution uses private and public keys stored in the IETF standard Secure Shell v2 format. However, Tectia Client and Server can also use keys and related files in the OpenSSH format and OpenSSL PEM format.

The following OpenSSH/OpenSSL-PEM keys are supported:

- server host key pair
- trusted server host public keys, which clients use to authenticate servers
- user private keys (used by clients to authenticate to a server)
- authorized user public keys (used by a server to authenticate users), including public-key options

4.2 Server Authentication with Public Keys

The server is authenticated with a digital signature based on an RSA, DSA, ECDSA, or Ed25519 public-key algorithm. At the beginning of the connection, the server sends its public key to the client for validation.

Server authentication is done during Diffie-Hellman key exchange through a single public-key operation. When public-key authentication is used to authenticate the server, the first connection is very important. During the first connection the client will display a message similar to the one in Figure 4.2.
Caution

Never save a host public key without verifying its authenticity!

To help you to verify the identity of the server host, the message displays a fingerprint of the host’s public key. The fingerprint is represented using the SSH Babble format, and it consists of a series of pronounceable five-letter words in lower case and separated by dashes.

Verify the validity of the fingerprint, for example by contacting the administrator of the remote host computer (preferably by telephone) and asking the administrator to verify that the key fingerprint is correct. If the fingerprint is not verified, it is possible that the server you are connecting to is not the intended one (this is known as a man-in-the-middle attack).

After verifying the fingerprint, it is safe to continue connecting. Relevant information about the server public key will then be stored on the client-side machine. On Tectia Client on Unix it is stored in the $HOME/.ssh2/hostkeys directory. On Tectia Client on Windows it is stored in the %APPDATA%\SSH\HostKeys directory.

The stored information on the host keys is used in subsequent connections to those remote hosts. Tectia Client checks which type of a host key (DSA, RSA, ECDSA or Ed25519) it possesses for a particular server, and automatically chooses the key exchange algorithm to be used in the connection between the client and server accordingly. This makes it quicker to connect to hosts for which only one type of host key has been stored.

When auth-server-publickey is set to some other policy than strict (as it is by default), if logging is enabled for the Connection Broker, Tectia Client will log information about changed and new host public keys with their fingerprints in the syslog (on Unix) or Event Viewer (on Windows).

4.2.1 Host Key Storage Formats

When the host key is received during the first connection to a remote host (or when the host key has changed) and you choose to save the key, its file name is stored in hashed format, keys_hhh..., where
hhh is a hash of the host port and name. The saved file contains a hash of the host’s public key. A salt is included in the hash calculations. The value of the salt is stored in the file salt in the same directory as the host keys ($HOME/.ssh2/hostkeys on Unix, %APPDATA%\SSH\HostKeys on Windows). The hashed host key format is a security feature to make address harvesting on the hosts difficult.

In the plain (traditional) format, the name of a host key file includes the host’s name and port, as in key_22_host.example.com.pub, and the file contains the host’s public key in plaintext format.

The storage format can be controlled with the filename-format attribute of the known-hosts element of the ssh-broker-config.xml configuration file. The attribute value must be plain or hash (default).

If you are adding the keys manually, the keys should be named with the key_<port>_<host>.pub pattern, where <port> is the port the Secure Shell server is running on and <host> is the host name you use when connecting to the server (for example, key_22_alpha.example.com.pub).

If both the hashed and plaintext format keys exist, the hashed format takes precedence.

Note that the host identification is different based on the host name and port the client is connecting to. The host name can occur in four different formats:

- Fully qualified domain name (FQDN)
- Short host name
- IPv4 address
- IPv6 address

The host key for each name format has to be saved separately, as they are not mutually exchangeable.

The host key is saved under the host name format used in the login. For example, if you want to use all the host name formats when connecting to a remote host named alpha, connect to the host first with the following commands and save the host key under all four names:

- sshg3 user@alpha
  produces the key with the short host name (in plain format key_22_alpha.pub)
- sshg3 user@alpha.example.com
  produces the key with FQDN (in plain format key_22_alpha.example.com.pub)
- sshg3 user@10.1.101.10
  produces the key with IPv4 address (in plain format key_22_10.1.101.10.pub)
- sshg3 user@fd00:10:1:103::1:2f69
  produces the key with IPv6 address (in plain format key_22_fd0001000101030000000000012f69.pub)
When connecting to a server using its IPv6 address, the IPv6 address given to Tectia Client is canonicalized without the colons, and the canonical format is used in the known host key file name. For example, the plain format host key file for ::1#10022 would be key_10022_000000000000000000000000000000001.pub. The canonical format is also used in the process of saving and reading hashed host keys.

Also if you need to connect to the same host but different port, your client needs a separate host key for that purpose; for example key_22_alpha.pub and key_222_alpha.example.com.pub.

After the first connection, the locally stored information about the server public key will be used in server authentication.

### 4.2.2 Using the System-Wide Host Key Storage

If a host key is not found in the user-specific host key directory, it is next searched on Unix from the /etc/ssh2/hostkeys directory, on pre-Vista Windows from the \C:\Documents and Settings\All Users\Application Data\SSH\HostKeys directory, and on Windows Vista and later Windows versions from the \C:\ProgramData\SSH\HostKeys directory. Host key files are not automatically put in the system-wide directory but they have to be updated manually by the system administrator (root).

The process for distributing the host keys manually is explained in the following. The instructions reflect the Unix file paths but are applicable also to Windows. Simply replace the Unix paths with the corresponding Windows paths.

#### Storing Keys in the Hashed Format

To obtain and store hashed remote host keys in the system-wide storage:

1. Select a client-side user whose $HOME/.ssh2/hostkeys will be the basis for the system-wide /etc/ssh2/hostkeys. The user should have administrative privileges, as placing the keys to the system-wide location requires them.

   The same user account must also be used to maintain the system-wide /etc/ssh2/hostkeys later on if the host key on some server changes. The process is to maintain the user's host keys in the $HOME/.ssh2/hostkeys directory and then replicate the changes to the system-wide /etc/ssh2/hostkeys directory.

2. Make sure that the $HOME/.ssh2/hostkeys directory is empty when obtaining the keys for the first time, or that the saved host keys are intentional.

   If you need to obtain new keys later, the same $HOME/.ssh2/hostkeys/salt file has to be used.

3. Connect with Tectia Client to the remote server, verify the fingerprint, and save the key.

   Repeat this step as many times as there are remote servers. Note that you do not have to complete the user authentication, only the key exchange part of the Secure Shell connection.

4. Once you have obtained all the host keys you wish to maintain in the system-wide location, place the keys to the system-wide location, for example by running the following commands:
# mkdir /etc/ssh2/hostkeys
# cp -p $HOME/.ssh2/hostkeys/* /etc/ssh2/hostkeys

Note that also the salt file ($HOME/.ssh2/hostkeys/salt) has to be copied so that Tectia Client is able to identify the hashed host keys. Also if multiple users contribute to the system-wide /etc/ssh2/hostkeys directory, they have to share the same salt file.

After creating the system-wide location for host keys, you can maintain it by using the ssh-keygen-g3 tool.

The following copy examples show the most frequently needed commands for host key storage maintenance. The commands use the user-specific hostkey storages ($HOME/.ssh2/hostkeys and possibly the $HOME/.ssh/known_hosts file) as the source. If keys are to be copied from a different source, you need to append an appropriate --hostkeys-directory or --hostkey-file option to the command.

To copy the key of a new host called 'alpha' from the user-specific hostkey storage to the system-wide directory, enter command:

```
# ssh-keygen-g3 --append=no --overwrite=no --copy-host-id alpha /etc/ssh2/hostkeys
```

In this case, because of --overwrite=no, if a key for server 'alpha' already exists, the command will fail and the key will not be updated.

To add additional keys to a known host, enter command:

```
# ssh-keygen-g3 --append=yes --copy-host-id alpha /etc/ssh2/hostkeys
```

To update the key of a known host, enter command:

```
# ssh-keygen-g3 --append=no --copy-host-id alpha /etc/ssh2/hostkeys
```

To remove a host from the known hosts list, enter command:

```
# ssh-keygen-g3 --hostkeys-directory /etc/ssh2/hostkeys --delete-host-id alpha
```

For more detailed information on the ssh-keygen-g3 tool, see ssh-keygen-g3(1).

### Storing Keys in the Plain Format

To obtain and store traditional remote host keys in the system-wide storage:

1. As a server-side user, copy the /etc/ssh2/hostkey.pub file from the server as key_<port>_<hostname>.pub to the /etc/ssh2/hostkeys/ directory on the client.

   You can do this as a non-privileged user on the server but you must be a privileged user, for example root, on the client.

2. Use secure means to transfer the file or verify that the fingerprint matches after the transfer with the ssh-keygen-g3 option -F (or --fingerprint), for example on Tectia Server on Unix:

   ```
   $ ssh-keygen-g3 -F /etc/ssh2/hostkey.pub
   ```
On the client:

```bash
# ssh-keygen-g3 -F /etc/ssh2/hostkeys/key_<port>_<hostname>.pub
```

Note that the identification is different based on the host and port the client is connecting to. Also connection with IP is considered a different host as well as connection to same host but different port. You can copy the same traditional `key_<port>_<hostname>.pub` to all these different names.

### 4.2.3 Resolving Hashed Host Keys

Tectia Client includes a tool to resolve which hashed host key belongs to which server. As there can be several server host keys stored on the client-side host, and the file name does not show the server name, it is sometimes necessary to check if a certain server public key is stored on the client host.

In Tectia Connections Configuration GUI, the tool is available on the Host Keys page. See the section called “Managing Host Keys”.

On the command line, the command syntax is:

```bash
ssh-keygen-g3 -F host_name[#port]
```

For example:

```bash
ssh-keygen-g3 -F examplehost#222
```

The `host_name` can be the fully qualified domain name, short host name, or the IP address of the remote host. The `port` definition is optional in the command. If no port is given, the default Secure Shell port 22 is assumed.

The tool shows the location, fingerprint (in the SSH babble format) and type (RSA, DSA, ECDSA or Ed25519) of the requested host's public key or keys. For example:

```bash
ssh-keygen-g3 -F examplehost
Fingerprint for key 'examplehost':
 (from location
  /home/user44/.ssh2/hostkeys/keys_bf53882dc47bb767edf161a4f636917f8358d635)
xuvin-zitil-ducid-gevil-vysok-buviz-nynun-pinat-tylev-gusez-dyxix (RSA)
```

If no keys are found for the given server, the `ssh-keygen-g3 -F` command will report where it looked for the keys, and will conclude as follows:

```bash
/ No keys found from any key directories or known_hosts files.
```

You can define several file locations to be checked for host keys. For more information, see Section 4.2.4.

### 4.2.4 Using the OpenSSH known_hosts File

Tectia Client supports also the OpenSSH-style known_hosts file that contains the public key data of known server hosts, and reads the file by default from the default location, from the user-specific file `$HOME/.ssh/known_hosts` or from the system-wide file `/etc/ssh/ssh_known_hosts`. Both hashed and plain-format host keys are supported.
In case you wish to define other files to be used for the known host keys, you can specify the files in the Connection Broker configuration file `ssh-broker-config.xml` by using the `known-hosts` element. Several file locations can be defined to be checked for known host keys, and the Connection Broker will read them in the order they are defined in the `ssh-broker-config.xml` file. Since the configuration file settings will override the default behavior, you need to define also the default locations of the OpenSSH-style `known_hosts` file, in case you want them all to be read. For example:

```xml
<general>
  ...
  <known-hosts path="/home/username/.ssh/known_hosts" />
  <known-hosts path="/etc/ssh/ssh_known_hosts" />
  <known-hosts path="/home/.ssh2/hostkeys" />
  <known-hosts path="/u/username/.ssh2/hostkeys" />
</general>
```

You can disable OpenSSH `known_hosts` file handling by defining an empty setting: `known-hosts path=""`. After this, only the Tectia-related hostkey directories will be used.

The OpenSSH `known_hosts` file is never automatically updated by Tectia Client. New host keys are always stored in the Tectia `$HOME/.ssh2/hostkeys` directory or in the directory configured as the last one in `ssh-broker-config.xml`. See `known-hosts` for details.

### 4.3 Server Authentication with Certificates

Server authentication with certificates happens similarly to server authentication with public keys, except that the possibility of a man-in-the-middle attack during the first connection to a particular server is eliminated. The signature of a certification authority in the server certificate guarantees the authenticity of the server certificate even in the first connection.

A short outline of the server authentication process with certificates is detailed below:

1. The server sends its certificate (which contains a public key) to the client. The packet also contains random data unique to the session, signed by the server's private key.
2. As the server certificate is signed with the private key of a certification authority (CA), the client can verify the validity of the server certificate by using the CA certificate.
3. The client checks that the certificate matches the name or the IP address of the server. When endpoint identity check is enabled in the Connection Broker configuration (either in the `ssh-broker-config.xml` file with the `cert-validation` attribute `end-point-identity-check`, or in the Tectia Connections Configuration GUI CA Certificates page with the Enable endpoint identity check option) the client compares the server's host name or IP address to the Subject Name or Subject Alternative Name (DNS Address) specified in the server certificate.

If endpoint identity check is disabled in the Connection Broker configuration, the fields in the server host certificate are not verified and the certificate is accepted based on the validity period and CRL check only.
**Caution**

Disabling the endpoint identity check on the client is a security risk. Then anyone with a certificate issued by the same trusted CA that issues the server host certificates can perform a man-in-the-middle attack on the server.

Endpoint identity check can also be configured to make Tectia Client ask the user to either accept or cancel the connection if the server's host name does not match the one in the certificate.

4. The client verifies that the server has a valid private key by checking the signature in the initial packet.

During authentication the system checks that the certificate has not been revoked. This can be done either by using the Online Certificate Status Protocol (OCSP) or a certificate revocation list (CRL), which can be published either in an LDAP or HTTP repository.

OCSP is automatically used if the certificate contains a valid Authority Info Access extension, or an OCSP responder has been separately configured. If no OCSP responder is defined or the OCSP connection fails, CRLs are used. If LDAP is used as the CRL publishing method, the LDAP repository location can also be defined in the `ssh-broker-config.xml` file.

### 4.3.1 Managing CA Certificates with the Configuration File (Unix)

When configuring the client, it must be set up to trust the CA certificate and to access the certificate revocation list (CRL).

To configure the client to trust the server's certificate, perform the following tasks:

1. Copy the CA certificate(s) to the client machine. You can either copy the X.509 certificate(s) as such, or you can copy a PKCS #7 package including the CA certificate(s).

   Certificates can be extracted from a PKCS #7 package by specifying the `-7` flag with `ssh-keygen-g3`.

2. Define the CA certificate(s) to be used in host authentication in the `ssh-broker-config.xml` file under the `general` element:

   ```xml
   <cert-validation end-point-identity-check="yes"
       http-proxy-url="http://proxy.example.com:800">
     <ldap-server address="ldap://ldap.example.com:389"/>
     <ocsp-responder url="http://ocsp.example.com:8090" validity-period="0"/>
     <dod-pki enable="no"/>
     <ca-certificate name="ssh_ca1"
         file="ssh_ca1.crt"
         disable-crls="no"
         use-expired-crls="100"/>
   </cert-validation>
   ``

   The client will only accept certificates issued by the defined CA(s).

   You can disable the use of CRLs by setting the `disable-crls` attribute of the `ca-certificate` element to `"yes".`
Note

CRL usage should only be disabled for testing purposes. Otherwise it is highly recommended to always use CRLs.

Also define the LDAP server(s) or OCSP responder(s) used for CRL checks. Defining the LDAP server is not necessary if the CA certificate contains a CRL distribution point extension.

3. If the CA services (OCSP, CRL) are located behind a firewall, define also the SOCKS server in the ssh-broker-config.xml file. The SOCKS server is defined inside cert-validation with the socks-server-url element.

4.3.2 Managing CA Certificates with the GUI

Using the Tectia Connections Configuration GUI to manage CA certificates is described in the section called “Managing CA Certificates”.

4.4 User Authentication with Passwords

The password authentication method is the easiest to implement, as it is set up by default. Since all communication is encrypted, passwords are not available for eavesdroppers.

On a Unix system, password authentication uses the /etc/passwd or /etc/shadow file, depending on how the passwords are set up. The shadow password files can be used on Linux and Solaris servers, but not on HP-UX or AIX servers.

On Windows, password authentication uses the Windows password to authenticate the user at login time. Also, if the SSH server allows it, users with administrator privileges may retain their permissions by adding elevated, before their user name. For example:

```
$ sshg3 elevated,Administrator@example.com
```

4.4.1 Defining Password Authentication with the Configuration File (Unix)

To enable password authentication on the client, the authentication-methods element of the ssh-broker-config.xml file must contain an auth-password element:

```
<authentication-methods>
 ...
 <auth-password />
 ...
</authentication-methods>
```

Other authentication methods can be listed in the configuration file as well. Place the least interactive method first.

4.4.2 Using Stored Passwords in Connection Profiles
In connection profiles that will be used in non-interactive connections, it is also possible to use passwords stored to the Tectia Client configuration or to the system.

In the Connection Broker configuration file `ssh-broker-config.xml`, the stored passwords are configured with the `password` element, with the following syntax:

```xml
<profiles>
  <profile>
    <authentication-methods>
      <auth-password />
    </authentication-methods>
    ... 
    <password file="path/to/file" /> 
  </profile>
  ...
</profiles>
```

The `password` element can be used to specify a user password that the client will send as a response to password authentication.

The password can be given directly in the `string` attribute, but safer alternatives are to define either a path to a file containing the password in the `file` attribute, or to use the `command` attribute to define a path to a program or script that outputs the password.

When using the `command` attribute to refer to a shell script, make sure the script also defines the user's shell, and outputs the actual password. Otherwise the executed program fails, because it does not know what shell to use for the shell script. For example, if the password string is defined in a file named `my_password.txt`, and you want to use the bash shell, include these lines in the script:

```bash
#!/usr/bash
cat /full/pathname/to/my_password.txt
```

**Caution**

If the password is given using this option, it is extremely important that the `ssh-broker-config.xml` file, the password file, or the program are not accessible by anyone else than the intended user.

**Note**

Any password given with the command-line options will override this setting.

Via the Tectia Connections Configuration GUI, the stored passwords are configured on the **Connection profiles → Authentication** tab. Select **Store password for non-interactive use** and define the password or the path to the password file or program.

**Caution**

If you choose to use stored passwords, it is extremely important that the Tectia Client host and the password file or program are not accessible by anyone else than the intended user.
To store the password as such in the configuration, enter the password directly in the **Password** field.

To use a file containing the password, select **Password file** and enter the path to the file in the field.

To use a program or a script that outputs the password, select **Password program** and enter the path to the program in the field.

**Note**

The user is required to have adequate permissions to the password file and to the password program. The file or the program executable must be owned by the user, local administrator or a member in the local admin group, and the file must have the `allow-type` permissions for administrators.

### 4.4.3 Managing Authentication Methods with the GUI

Using the Tectia Connections Configuration GUI to manage authentication methods is described in the section called “Defining Authentication”.

---

© 1995–2021 SSH Communications Security

Corporation

Tectia® Client 6.4 User Manual
4.5 User Authentication with Public Keys

Public-key authentication is based on the use of digital signatures. Each user creates a pair of key files. One of these key files is the user's public key, and the other is the user's private key. The server knows the user's public key, and only the user has the private key.

The key files must be stored in a location where the user has the write rights, (and read rights), but that is not accessible to others. These user-specific rights are required for the key.pub file, the authorized_keys directory, and for the authorization file, if used.

When the user tries to authenticate, the client sends a signature to the server, and the server checks for matching public keys. If the key is protected with a passphrase, the server requests the user to enter the passphrase.

Remember that your private-key file is used to authenticate you. Keep your private-key file in a secure place and make sure that no one else has access to it. If anyone else can access your private-key file, they can attempt to log in to the remote host computer pretending to be you. Define a passphrase to protect your private key, whenever possible. On a machine shared by several users, make sure that the permission settings do not allow others to access your private key.

Caution

Do not store your private keys in a location accessible to other users.

Also note that if you are using the Windows roaming profiles functionality, your personal settings will be replicated with the roaming profile server. If you store your private keys in the default location (under the profile folder of your Windows user account) your private keys may be susceptible to a malicious user listening to the network traffic. Therefore the User Settings folder should not be a directory that is used in profile roaming.

To use public-key authentication with Tectia Client, do the following actions:

1. Generate a key pair. You can generate your own key files with the help of a built-in Public-Key Authentication Wizard on Windows (see Section 4.5.3), or with ssh-keygen-g3 on Unix or Windows command line (see Section 4.5.1).

   You can also import existing keys on the Keys and Certificates page of the Tectia Connections Configuration GUI. See the section called “Managing Keys and Certificates”.

2. Upload your public key to the remote host computer. On Windows, you can do this automatically (see the section called “Uploading Public Keys Automatically”). On Unix and Windows, you can also copy the public key manually (see Section 4.5.2).

In the instructions in the following sections,

- Server is the remote host running the Secure Shell server that you are trying to connect to.

- ServerUser is the user name on Server that you are logging in as.
• **Client** is the host running the Secure Shell client (Tectia Client).

• **ClientUser** is the user name on **Client** that should be allowed to log in to **Server** as **ServerUser**.

![Tectia Client](image)

**Figure 4.4. User public-key authentication**

The instructions assume that **ClientUser** is allowed to log in to **Server** as **ServerUser** using some other authentication method (usually password).

### 4.5.1 Creating Keys with `ssh-keygen-g3`

To create a public key pair, run `ssh-keygen-g3` on **Client**:

```
$ ssh-keygen-g3
Generating 2048-bit rsa key pair
9 oOo.0Oo.00o
Key generated.
2048-bit rsa, ClientUser@Client, Wed Feb 2 2016 12:09:46 +0200
Passphrase:
Again:
Private key saved to /home/ClientUser/.ssh2/id_rsa_2048_a
Public key saved to /home/ClientUser/.ssh2/id_rsa_2048_a.pub
```

When run without options, `ssh-keygen-g3` asks for a passphrase for the new key. Enter a sufficiently long (20 characters or so) sequence of any characters (spaces are OK).

**Note**

In FIPS mode, due to a FIPS regulation which forbids exporting unencrypted private keys out of the FIPS module, it is not possible to generate user keys without a passphrase.

The new authentication key pair consists of two separate files. One of the keys is your private key which must never be made available to anyone but yourself. The private key can only be used together with the passphrase.

On Unix, the key pair is by default stored in your `$HOME/.ssh2` directory (created by `ssh-keygen-g3` if it does not exist previously). On Windows, the key pair is by default stored in your `%APPDATA%\SSH\UserKeys` directory.

In the example above, the private key file is `id_rsa_2048_a`. The public key file is `id_rsa_2048_a.pub`, and it can be distributed to other computers.
By default, `ssh-keygen-g3` creates a 2048-bit RSA key pair. DSA, ECDSA or Ed25519 keys can be generated by specifying the `-t` option with `ssh-keygen-g3`. Key length can be specified with the `-b` option. For automated jobs, the key can be generated without a passphrase with the `-P` option, for example:

```bash
$ ssh-keygen-g3 -t ecdsa -b 384 -P
```

For more information on the `ssh-keygen-g3` options, see `ssh-keygen-g3(1)`.

### 4.5.2 Uploading Public Keys Manually

All commands in this section are shown using `sshg3` and `scpg3` from the machine running Tectia Client. Server-side configuration can also be done by logging in to the remote server and entering the commands locally.

To enable public-key authentication with your key pair:

1. **Place your keys in a directory where the Connection Broker can locate them.**
   
   By default, the Connection Broker attempts to use each key found in the `$HOME/.ssh2` directory on Unix, or in the `%APPDATA%\SSH\UserKeys` and `%APPDATA%\SSH\UserCertificates` directories on Windows.

   You can also add other directory locations for keys on the **Keys and Certificates** page of the Tectia Connections Configuration GUI. See the section called “Managing Keys and Certificates”. On Unix, you can use the `general/key-stores/key-store` element in the `ssh-broker-config.xml` file. See the section called “Key Store Configuration Examples”.

2. **(Optional) Create an identification file.**

   Using the `identification` file is not necessary if all your keys are stored in the default directory and you allow all of them to be used for public-key and/or certificate authentication. If the `identification` file does not exist, the Connection Broker attempts to use each key found in the default directory. If the `identification` file exists, the keys listed in it are attempted first.

   Create a file called `identification`, on Unix in your `$HOME/.ssh2` directory, or on Windows in your `%APPDATA%\SSH` directory.

   Edit it with your favorite text editor to include the following line (replace `id_rsa_2048_a` with the file name of the private key):

   ```plaintext
   IdKey       id_rsa_2048_a
   ```

   The keys are assumed to be in the same directory with the `identification` file, but also an absolute or a relative path can be given. For example, on Windows:

   ```plaintext
   IdKey       UserKeys\id_rsa_2048_a
   ```

   The identification file can contain several key IDs. For more information on the syntax of the identification file, see `$HOME/.ssh2/identification`.  

© 1995–2021 SSH Communications Security Corporation
3. Connect to Server using some other authentication method and create a .ssh2 (and .ssh2/authorized_keys), or a .ssh directory under your home directory if it does not exist already.

Depending on the server version the remote host is running, run one of the following commands:

- **Tectia Server on Unix or z/OS:**
  
  
  ```
  $ sshg3 ServerUser@tectia_server mkdir .ssh2
  ```

  If you do not want to use an authorization file on Tectia Server 5.x or later on Unix, create also the authorized_keys directory:

  ```
  $ sshg3 ServerUser@tectia_unix mkdir .ssh2/authorized_keys
  ```

- **Tectia Server on Windows:**

  ```
  $ sshg3 ServerUser@tectia_win "cmd /c mkdir .ssh2"
  ```

  If you do not want to use an authorization file on Tectia Server 5.x or later on Windows, create also the authorized_keys directory:

  ```
  $ sshg3 ServerUser@tectia_win "cmd /c mkdir .ssh2\authorized_keys"
  ```

- **OpenSSH server on Unix or z/OS:**

  ```
  $ sshg3 ServerUser@open_server mkdir .ssh
  ```

4. Copy the public key to Server.

Depending on the server version the remote host is running, do one of the following actions:

- **Tectia Server 5.x or later on Unix and Windows:**

  Use SCP to upload your public key to the server, to your authorized_keys directory (by default $HOME/.ssh2/authorized_keys on Unix servers, or %USERPROFILE%/.ssh2/authorized_keys on Windows servers):

  ```
  $ scpg3 id_rsa_2048_a.pub ServerUser@tectia_server:.ssh2/authorized_keys/
  ```

- **Tectia Server 4.x on Unix and Windows:**

  Use SCP to upload your public key to the server (by default to the $HOME/.ssh2 directory on Unix and to the %USERPROFILE%/.ssh2 directory on Windows servers):

  ```
  $ scpg3 id_rsa_2048_a.pub ServerUser@tectia4x_server:.ssh2/
  ```

- **Tectia Server for IBM z/OS:**

  The public key must be converted to the EBCDIC format. This can be done by including the `scpg3 dst-site` command-line option, or the `sftpg3 site` commands in the file transfer command. For more information on the site parameters, see Section 5.3.1.

  Use SCP to upload your public key to the server (by default to the $HOME/.ssh2 directory):

  ```
  $ scpg3 --dst-site="C=ISO8859-1,D=IBM-1047,X=TEXT" id_rsa_2048_a.pub \
  ```
• OpenSSH server on Unix:

Use SCP to upload your public key to the server, to your $HOME/.ssh directory:

$ scp id_rsa_2048_a.pub ServerUser@open_unix:.ssh/

5. Create an authorization or authorized_keys file on Server.

Depending on the server version the remote host is running, do one of the following actions:

• Tectia Server 5.x or later on Unix and Windows do not require an authorization file if the public keys are stored in the user's authorized_keys directory. However, an authorization file may be optionally used. See instructions for creating the file below in the Tectia Server 4.x information.

• Tectia Server 4.x on Unix and Windows and Tectia Server for IBM z/OS require an authorization file stored in the user's .ssh2 directory. The authorization file specifies the public keys that are authorized for login.

Add the key entry to the authorization file. On a Unix or z/OS server:

$ sshg3 ServerUser@tectia_server "echo Key id_rsa_2048_a.pub >> .ssh2/authorization"

On a Windows server:

$ sshg3 ServerUser@tectia4x_win "cmd /c echo Key id_rsa_2048_a.pub >> .ssh2\authorization"

An example authorization file is shown below (by default $HOME/.ssh2/authorization on Unix and z/OS servers, and %USERPROFILE%\ssh2\authorization on Windows servers):

<table>
<thead>
<tr>
<th>Key</th>
<th>id_rsa_2048_a.pub</th>
</tr>
</thead>
</table>

This directs Tectia Server to use id_rsa_2048_a.pub as a valid public key when authorizing your login.

• OpenSSH server requires that the public key is converted to the OpenSSH public-key file format and stored in the authorized_keys file in the user's .ssh directory.

Convert the public key to the OpenSSH public-key file format on the server and append it to your $HOME/.ssh/authorized_keys file. This can be done with a remote command on an OpenSSH server as follows:

$ sshg3 ServerUser@open_server "ssh-keygen -i -f id_rsa_2048_a.pub >> .ssh/authorized_keys"

6. Make sure that public-key authentication is enabled in the ssh-broker-config.xml file (it is enabled by default).

```xml
<authentication-methods>
  <auth-publickey />
  ...
</authentication-methods>
```
Other authentication methods can be listed in the configuration file as well. Place the least interactive method first.

Assuming Server is configured to allow public-key authentication to your account, you should now be able to log in from Client to Server using public-key authentication.

Try to log in:

Client$ sshg3 Server

You should be prompted for the passphrase of the private key. After you have entered the passphrase, a Secure Shell connection will be established.

### 4.5.3 Creating Keys with the Public-Key Authentication Wizard

On Windows and Linux, you can use the Tectia Public-Key Authentication Wizard to generate a key pair and to upload a public key to a host, see the section called “Public-Key Generation” and the section called “Uploading Public Keys Automatically”. The wizard will generate two key files, your private key and your public key.

The new private and public key will be stored on your local computer in the %APPDATA%\SSH\UserKeys directory on Windows and in the $HOME/.ssh2/authorized_keys directory on Linux. The private key file has no file extension, and the public key has the same base file name as the private key, but with .pub as the file extension.

Make sure that public-key authentication is allowed in the Connection Broker configuration, in the default settings and in the relevant connection profile (it is allowed by default). For the default settings, see the section called “Defining Authentication”, and for the connection profile, see the section called “Defining Authentication”.

To use the key pair for public-key authentication, you have to upload the public key to the remote host computer. If the remote host has an SFTP server running, you can automatically upload a copy of your new public key to the server with the wizard. To upload the key automatically, see the section called “Uploading Public Keys Automatically”. To upload the key manually, see Section 4.5.2.

**Public-Key Generation**

New keys are generated in the Tectia Connections Configuration GUI. Under User authentication, select the Keys and Certificates page and click New Key to start the Public-Key Authentication Wizard.
Figure 4.5. The Public-Key Authentication Wizard

Define the key properties and the required passphrase to protect your key pair; you will be requested to enter the passphrase always when using the keys to authenticate yourself.

**File name**

Type a unique name for the key file. Tectia Client suggest a name consisting of the user name and the host name.

**Comment**

In this field you can write a short comment that describes the key pair. You can for example describe the connection the keys are used for. This field is not obligatory, but helps to identify the key later.

**Passphrase**

Type a phrase that you have to enter when handling the key. This passphrase works in a similar way to a password and gives some protection for your private key.

**Note**

In FIPS mode, due to a FIPS regulation which forbids exporting unencrypted private keys out of the FIPS module, it is not possible to generate user keys without a passphrase.

Make the passphrase difficult to guess. Use at least 8 characters, both letters and numbers. Any punctuation characters can be used as well.
Memorize the passphrase carefully, and do not write it down.

**Retype passphrase**

Type the passphrase again. This ensures that you have not made a typing error.

Click [Advanced Options](#) to define the type of the key to be generated and the key length to be different from the defaults. By default, Tectia Client generates a pair of 2048-bit RSA keys.

In the **Key Properties** fields, you can make the following selections:

**Key type**

Select the type of the key to be generated. Available options are DSA, RSA (default), ECDSA and Ed25519.

**Note**

Ed25519 keys are not available in FIPS mode.

**Key length**

Select the length (complexity) of the key to be generated. Available options are:

- DSA/RSA keys: 1024, 2048, 3072, 4096, 5120, 6144, 7168, 8192 bits

**Note**

In FIPS mode (conforming to FIPS 186-3) the available DSA key lengths are limited to 1024, 2048 and 3072 bits.

- ECDSA keys: 256, 384, 521 bits
- Ed25519 keys: 512 bits

Larger keys of the same key type are more secure, but also slower to generate. A 256-bit ECDSA key and a 3072-bit DSA or RSA key provide equivalent security.

Click **Next** to proceed to uploading the key as instructed in the section called “Uploading Public Keys Automatically”.

**Uploading Public Keys Automatically**

Public keys can be uploaded automatically to servers that have the SFTP subsystem enabled. The **Public-Key Authentication Wizard** automatically uploads each new public key to a remote host of your choice. The wizard lists all existing keys, and you can select a key to upload it also to other remote servers at any time.

To access the **Public-Key Authentication Wizard**, click **User Authentication → Keys and Certificates** on the tree view.

Select a key from the **Key and Certificate List** and click **Upload**.
In the **Upload Public Key** view of the wizard, define the remote host where to upload the key:

![Public-key Authentication Wizard](image)

**Figure 4.6. Uploading a key**

**Quick connect**

Select this option to define the remote **Host name** and your **User name** there. The default Secure Shell port is 22.

**Connection profile**

Select from the drop-down list the connection profile that specifies the desired remote host and user name.

Click **Upload** to upload the key to the selected server. If you are already connected to the remote server host, the key upload starts immediately. If you are not connected, you will be prompted to authenticate on the server (by default with password).

The public key will be uploaded to the default user home directory (**%USERPROFILE%\.ssh2** on Windows, **$HOME/.ssh2** on Unix).

**Note**

The key user is required to have the `write` permissions to the key directory on the server, otherwise the automatic upload will fail. The administrator of the remote host computer may have restricted user access so that users are not able to configure public-key authentication for themselves even if public-key authentication is allowed in the server configuration.

Even if the automatic upload succeeds, it is possible that the server administrator has configured the system to store keys elsewhere than under the user home directory. In this case the keys and the authorization file additions have to be moved manually to the proper directory.

If you do not use the automatic upload facility, see Section 4.5.2.
4.5.4 Using Keys Generated with OpenSSH

Tectia Client supports also user key pairs generated with OpenSSH. The OpenSSH keys can be specified in the ssh-broker-config.xml file by using the `key-stores` element. An example configuration is shown below:

```xml
<key-stores>
  <key-store type="software"
    init="key_files(/home/exa/keys/id_rsa.pub,/home/exa/keys/id_rsa)" />
  <key-store type="software"
    init="directory(path(/home/exa/.ssh))" />
</key-stores>
```

This example adds a key called `id_rsa` and all keys from the user's default OpenSSH key directory (`.ssh` under the user's home directory).

You can add OpenSSH keys and directories on the Keys and Certificates page of the Tectia Connections Configuration tool. See the section called “Managing Keys and Certificates”.

The public key can be uploaded to the server the same way as with standard SSH2 keys. See Section 4.5.2 and the section called “Uploading Public Keys Automatically”.

4.5.5 Special Considerations with Windows Servers

If you use public-key authentication to log on to a Windows domain user account on Tectia Server 5.1 or earlier, you must give your user name as `DOMAIN\user` when attempting logon. On Unix command line, the backslash has to be escaped, for example:

```bash
$ sshg3 DOMAIN\user@win-server
```

With Tectia Server 5.2 and later, this is not required. When logging on to a machine that runs Tectia Server 5.2 or later, and belongs to a Windows domain, the user account is by default assumed to be a domain account. If you want to log on to a local account instead, you have to specify the machine name as the "domain", for example on Windows command line:

```cmd
> sshg3 MACHINE\user@machine
```

4.6 User Authentication with Certificates

Certificate authentication is technically a part of the public-key authentication method. The signature created with the private key and the verification of the signature using the public key (contained in the X.509 certificate when doing certificate authentication) are done identically with conventional public keys and certificates. The major difference is in determining whether a specific user is allowed to log in with a specific public key or certificate. With conventional public keys, every server must have every user's public key, whereas with certificates the users' public keys do not have to be distributed to the servers - distributing the public key of the CA (self-signed certificate) is enough.

In brief, certificate authentication works as follows:

1. The client sends the user certificate (which includes the user's public key) to the server. The packet also contains data unique to the session and it is signed by the user's private key.
2. The server uses the CA certificate (and external resources as required) to check that the user's certificate is valid.

3. The server verifies that the user has a valid private key by checking the signature in the initial packet.

4. The server matches the user certificate against the rules in the server configuration file to decide whether login is allowed or not.

### 4.6.1 Using the Configuration File (Unix)

To configure the client to authenticate itself with an X.509 certificate, perform the following tasks:

1. Enroll a certificate for yourself. This can be done, for example, with the `ssh-cmpclient-g3` or `sshscepclient-g3` command-line tools.

   Example: Key generation and enrollment using `ssh-cmpclient-g3`:

   ```bash
   $ ssh-cmpclient-g3 INITIALIZE
   -P generate://ssh2:passphrase@rsa:2048/user_rsa \
   -o /home/user/.ssh2/user_rsa -p 62154:ssh \
   -s 'C=FI,O=SSH,CN=user;email=user@example.org' \
   -S http://fw.example.com:1080 http://pki.example.com:8080/pkix/ \n   'C=FI, O=SSH, CN=Test CA 1'
   ```

2. Place your keys and certificates in a directory where the Connection Broker can locate them.

   By default, the Connection Broker attempts to use each key found in the `$HOME/.ssh2` directory on Unix, or in the `%APPDATA%/SSH/UserKeys` and `%APPDATA%/SSH/UserCertificates` directories on Windows.

   You can also add other directory locations for keys on the **Keys and Certificates** page of the Tectia Connections Configuration tool. See the section called “Managing Keys and Certificates”. On Unix, you can use the `general/key-stores/key-store` element in the `ssh-broker-config.xml` file. See the section called “Key Store Configuration Examples”.

3. *(Optional)* Create an identification file.

   Using the identification file is not necessary if all your keys are stored in the default directory and you allow all of them to be used for public-key and/or certificate authentication. If the identification file does not exist, the Connection Broker attempts to use each key found in the default directory. If the identification file exists, the keys listed in it are attempted first.

   Specify the private key of your software certificate in the `$HOME/.ssh2/identification` file (the `CertKey` option works identically with the `IdKey` option):

   ```
   CertKey   user_rsa
   ```

   The certificate itself will be read from `user_rsa.crt`.

   For more information on the syntax of the identification file, see `$HOME/.ssh2/identification`. 
4. Make sure that public-key authentication is enabled in the `ssh-broker-config.xml` file (it is enabled by default).

```xml
<authentication-methods>
  <auth-publickey />
  ...
</authentication-methods>
```

Other authentication methods can be listed in the configuration file as well. Place the least interactive method first.

### 4.6.2 Configuring User Authentication with Certificates on Windows

You can configure user authentication with X.509 certificates on Windows using Tectia Connections Configuration GUI. You also need to configure Tectia Server for user authentication with certificates, see *Tectia Server Administrator Manual*.

1. Launch Tectia Connections Configuration GUI.

   Right-click ![right-click icon] in the notification area of the Windows taskbar and select **Configuration**.

2. Under **General**, click **Default Connection**. Select the **Authentication** tab. Ensure that public-key authentication is enabled and it is the first or only method in the list. By default, it is enabled.

   Under **Public-Key Authentication**, you can select to use public keys or certificates or both in the authentication.
3. If you are using connection profiles, select the profile name under Connection Profiles. Select the Authentication tab and ensure that public-key authentication is enabled.

4. Tectia suggests installing the certificate into the Microsoft Certificate store that is a personal store for the user.

5. Under User Authentication, select Key Providers. Enable Microsoft Crypto API and click Apply.
Figure 4.8. Enabling Microsoft Crypto API as a certificate provider

You can also read certificate information from USB tokens or smartcards via Microsoft Crypto API if they are compatible with the API. Alternatively USB tokens or smartcards can be used by enabling PCKS#11.

6. The certificate is now loaded into the client automatically. Under User Authentication, select Keys and Certificates. You can see the available certificates under Key and Certificate List.
Figure 4.9. Viewing available certificates

Tectia Client can also read key and certificate information from the file system. These can be defined under Additional Directories and Files.

**Note**

Ensure that the client certificate is set up for client authentication only. It makes troubleshooting several certificates easier, for example, as server authentication certificates cannot be used as user certificates.

For more information about the key and certificate settings, see the section called “Managing Keys and Certificates”.

**Troubleshooting User Authentication with Certificates**

If the certificate authentication does not succeed for some reason, running Tectia Server in the troubleshooting mode and viewing the troubleshooting log can provide a lot of information about the end-user connection. For more information, refer to Section Starting Tectia Server in Debug mode on Windows in the Tectia Server Administrator Manual.
4.6.3 Importing PKCS Certificates with Tectia Connections Configuration GUI

You can import existing PKCS #12, PKCS #7 and X.509 certificates on the Keys and Certificates page under User Authentication in the Tectia Connections Configuration GUI. See the section called “Managing Keys and Certificates”.

4.7 Host-Based User Authentication (Unix)

Host-based authentication uses the public host key of the client machine to authenticate a user to the remote server. Host-based authentication can be used with Tectia Client on Unix. The remote Secure Shell server can be either a Unix, Windows, or z/OS server.

Setting up host-based authentication usually requires administrator (root) privileges on the server. The setup is explained in the Tectia Server Administrator Manual.

**Note**

On AIX, for host-based authentication to work in FIPS mode, an administrator must copy the `libcrypto.a` file (or a symlink to it) to `/usr/lib/` or `/lib/`. This is required because on AIX, when a binary has the `setuid` (set user ID upon execution) access right flag, the linker is able to load libraries only from these two directories.

4.8 User Authentication with Keyboard-Interactive

Keyboard-interactive is a generic authentication method that can be used to implement different types of authentication mechanisms. Any currently supported authentication method that requires only the user’s input can be performed with keyboard-interactive.

The supported submethods of keyboard-interactive depend on the Secure Shell server. Commonly supported submethods include password, RSA SecurID, RADIUS, and PAM authentication.

**Note**

The client cannot request any specific keyboard-interactive submethod if the server allows several optional submethods. The order in which the submethods are offered depends on the server configuration. However, if the server allows, for example, the two optional submethods SecurID and password, the user can skip SecurID by pressing enter when SecurID is offered by the server. The user will then be prompted for a password.

4.8.1 Defining Keyboard-Interactive Method with the Configuration File (Unix)

To enable keyboard-interactive authentication on Tectia Client, make sure that you have the following line in the `ssh-broker-config.xml` file:
4.8.2 Defining Keyboard-Interactive Method with the GUI

Using keyboard-interactive authentication is a Connection Broker setting. Using the Tectia Connections Configuration GUI to manage authentication methods is described in the section called “Defining Authentication”.

4.9 User Authentication with GSSAPI

GSSAPI (Generic Security Service Application Programming Interface) is a function interface that provides security services for applications in a mechanism independent way. This allows different security mechanisms to be used via one standardized API. GSSAPI is often linked with Kerberos, which is the most common mechanism of GSSAPI.

On Linux platforms, Kerberos libraries are installed by default. They are also available for most other Unix platforms, but have to be installed separately.

For Windows, GSSAPI offers integrated authentication for Windows 2003 (or later) networks with Kerberos. This method utilizes domain accounts, since local accounts are not transferable across machine boundaries.

The GSSAPI authentication method has no user interface (besides configuration). It does not ask anything from the user. If something fails during GSSAPI exchange, the reason for the failure can be seen in the client debug log.

4.9.1 Defining GSSAPI Method with the Configuration File (Unix)

To enable GSSAPI authentication on the client, make sure that you have the following line in the ssh-broker-config.xml file:

```xml
<authentication-methods>
  <auth-gssapi />
  ...
</authentication-methods>
```

Other authentication methods can be listed in the configuration file as well. Place the least interactive method first.

4.9.2 Defining GSSAPI Method with the GUI

Using the Tectia Connections Configuration GUI to manage authentication methods is described in the section called “Defining Authentication”.

```xml
<authentication-methods>
  ...
  <auth-keyboard-interactive />
  ...
</authentication-methods>
```
Chapter 5 Transferring Files

Tectia Client and Tectia Server provide the basic secure file transfer functionality using the Secure File Transfer Protocol (SFTP).

This chapter gives instructions on secure file transfer using the SCP and SFTP command-line tools and the SFTP graphical user interface (GUI).

5.1 Secure File Transfer with scpg3 and sftpg3 Commands

Tectia Client provides commands scpg3 (secure copy) and sftpg3 for secure file transfer. These command-line clients apply the Secure File Transfer Protocol (SFTP).

When files are being uploaded with commands scpg3 and sftpg3, the files have the TRUNCATE flag on. The file size is shown as 0 until the file transfer has been completed.

These secure file transfer commands rely on the Connection Broker to take care of the cryptographic operations and authentication tasks, so they start the Connection Broker (the ssh-broker-g3 process) in run-on-demand mode, if the Connection Broker is not running already.

In case the scpg3 and sftpg3 command-line clients are used in scripts that start several file transfer commands at the same time, the Connection Broker must already be running in the background. Since the Connection Broker takes a few seconds to become up and running, make sure the scripts are not started immediately, because they can fail if the Connection Broker is still starting.

To start the Connection Broker, run the ssh-broker-g3 command. For more information, see ssh-broker-g3(1).

5.1.1 Using scpg3

scpg3 (scpg3.exe on Windows) is used to securely copy files over the network. scpg3 uses ssh-broker-g3 to provide a secure transport using the Secure Shell version 2 protocol. The remote host(s) must be running a Secure Shell version 2 server with the sftp-server (or sft-server-g3) subsystem enabled.

The basic syntax of scpg3 is:
**Chapter 5 Transferring Files**

scp3 user@source:/directory/file user@destination:/directory/file

scp3 can be used to copy files in either direction; from the local system to the remote system or vice versa. Copies between two remote hosts are also permitted. Local paths can be specified without the `user@system:` prefix. Relative paths can also be used, they are interpreted in relation to the user's home directory.

Windows paths should be preceded by a slash ("/ "). For example, copying a local file to a remote Windows server:

scp3 localfile user@destination:/C:/directory/file

For more information on the command-line options, see scp3(1).

### 5.1.2 Using sftpg3

sftpg3 (sftpg3.exe on Windows) is an FTP-like client that can be used for secure file transfers over the network. sftpg3 uses ssh-broker-g3 to provide a secure transport using the Secure Shell version 2 protocol.

Even though it functions like ftp, sftpg3 does not use any FTP daemon or FTP client for its connections. sftpg3 can be used to connect to any host that is running a Secure Shell version 2 server with the sftp-server (or sft-server-g3) subsystem enabled.

The basic syntax of sftpg3 is:

sftpg3 user@host

sftpg3 has two connection end points, local and remote, and both of them can be connected to other hosts than the Tectia Client host. By default, the local end point is connected to the file system of the Tectia Client host and the remote end point is connected to the host defined on the command line (or left unconnected if no host is defined on the command line).

When started interactively, sftpg3 displays a prompt where the SFTP commands can be entered, much like in the traditional ftp program. It is also possible to start sftpg3 non-interactively with a batch file that contains the commands to be run.

For more information on the command-line options and commands, see sftpg3(1).

### 5.1.3 Enhanced File Transfer Functions

The following enhanced file transfer features are available with the scp3 and sftpg3 command-line tools of Tectia Client:

- Checkpoint/restart for transferring large files (with any IETF-compliant SSH server)
- Prefix for ensuring that a file is fully transferred before it is used (with any IETF-compliant SSH server)
- Streaming for improved file transfer speed (with Tectia Servers)

For information on the commands, see scp3(1) and sftpg3(1).
5.2 Secure File Transfer GUI (Windows)

Tectia Client on Windows provides a secure file transfer GUI that makes it easy to download files from a remote host computer into your local computer and to upload files to a remote host. The Tectia Secure File Transfer GUI operates much like Windows Explorer.

![Figure 5.1. Tectia Secure File Transfer GUI](image)

In the Tectia Secure File Transfer GUI, you can use the connection profiles defined in the Connection Broker configuration, or connect to a remote host using the Quick Connect option.

5.2.1 Defining Secure File Transfer GUI Settings

Configuring the default settings for the Tectia Secure File Transfer GUI is explained in Section B.1.5.

5.2.2 Downloading Files with Tectia Secure File Transfer GUI

There are different ways to download a file, or several files at the same time. Selecting multiple files with the Shift or Control key works the same way as in Windows Explorer.

Drag and drop

Dragging and dropping is probably the easiest way to download files. Simply select the file(s) you want to download, hold down the mouse button and move the file to a location where you want it - for example on the Windows desktop - and release the button.

Download button

Click the Download button on the toolbar to download the selected file(s).
Shortcut menu

When you right-click a file in the Remote View, a shortcut menu appears. Select Download to perform the transfer immediately, or select Download Dialog to define another destination folder for the files.

If you selected the Download Dialog option, a Download - Select Folder dialog appears. This is a standard Windows file selection dialog, where you can select the location where you want the selected file(s) to be downloaded. After you have selected the appropriate folder (or some other location), the current downloading status will be shown in the Transfer View.

5.2.3 Uploading Files with Tectia Secure File Transfer GUI

The file transfer window can be used to upload files from your local computer to the remote host computer. There are different ways to upload a file, or several files at the same time. Selecting multiple files with the Shift or Control key works the same way as in Windows Explorer.

Drag and drop

Dragging and dropping is probably the easiest way to upload files. Simply click on the local file(s) you want to upload (for example on the desktop or Windows Explorer), hold down the mouse button, move the file(s) into the file view in the File Transfer window, and release the button.

Upload button

Click the Upload button on the file transfer window toolbar to upload the selected file(s).

Shortcut menu

When you right-click a file in the Local View, or an empty space in the Remote View, a shortcut menu appears. Select the Upload to perform the transfer immediately, or select Upload Dialog to select the files to upload.

If you have selected the Upload Dialog option, an Upload - Select Files dialog appears. This is a standard Windows file selection dialog, where you can select which file(s) you want to upload. After you have selected the files, the Transfer View shows the current uploading status.

5.2.4 Transfer and Queue Tabs

At the bottom of the Tectia File Transfer view, there are two tabs: Transfer and Queue. See Figure 5.1.

The Transfer tab displays a list of files that have already been transferred between the local and remote computers.

The Queue tab can be used to create a customized list of files that will be uploaded or downloaded at a later stage. You can use the mouse to drag and drop files to the Queue tab, where they will wait for a separate transfer command.
After logging in to a remote host, right-clicking the Queue page opens a shortcut menu with the following options:

- **Add** for adding selected files to the queue, right-click on the Queue page and select **Add**.

  The Edit Transfer Queue dialog appears. Click **New** above the list area to type in the path to a new file to be transferred, or click the ellipsis button (….) to browse to the files.

- To edit the target locations of the queued files, select a file to edit, right-click the Queue page and select **Edit**.

  The Edit Transfer Queue dialog opens, allowing you to type in a new destination directory for the file. You can also click the ellipsis button (…) to browse to the destination directory.

  You can use the **Edit** option for several files at the same time, but the direction of the transfer (upload or download) must be the same for all of the files.

- To delete files from the queue, select the files, right-click the Queue page and select **Remove**.

- To transfer single files, select them, right-click the Queue page and select **Transfer**.

- To transfer all the queued files, right-click the Queue page and select **Transfer All**.

### 5.2.5 Defining File Properties

Selecting a file in the Local View or Remote View and selecting **Operation → Properties** (or **Properties** on the shortcut menu) opens the File Properties dialog which allows you to view and change some of the file properties.

---

**Figure 5.2. Properties page for a file**
View and define the properties as necessary. You can modify for example the read-write permissions of
the file, or define the file as hidden.

For more information, see the operating system documentation.

5.2.6 Differences from Windows Explorer

The file transfer window operates very much the same way as Windows Explorer. However, due to the
different nature of handling files locally in your own computer (as per Windows Explorer) and handling
them over a secured remote connection in the host computer (as per Tectia Client file transfer), there are
some differences in operation.

Deleting folders

It is not possible to delete a remote folder that is not empty. Delete the files and subfolders in the
folder first.

Multiple paste operations

During copy and paste operations, the file names cannot be changed when the files are pasted.
Therefore it is not possible to paste files several times into one location, creating multiple copies of
the pasted files as in Windows Explorer.

Note

The maximum size of transferred files is limited only by the file system. (On many systems the
maximum file size is 2 gigabytes.)

5.3 Controlling File Transfer

The current Secure File Transfer Protocol (SFTP) does not transfer any information about the files to be
transferred, only the file contents as a byte stream. This is sufficient for Unix-type files if the sender and
receiver use the same CCS. However, it is possible to set specific file permissions for transferred files by
using the chmod command with command line tools.

With MVS data sets, Tectia needs more information: which transfer format to use, what code sets
are involved, and what the file characteristics are. Tectia introduces some extensions to SFTP and the
information can be relayed by using the Site commands of scpg3 and sftpg3.

For more information on MVS file transfers, see Tectia Server for IBM z/OS User Manual.

5.3.1 Site Command

For command descriptions, see the site and lsite command in sftpg3(1) and the --dst-site and --src-
site options in scpg3(1).

When giving the command, either the full parameter name or its abbreviation can be used. For example,
the following two commands accomplish the same thing:
sftp> site x-bin
sftp> site transfer_mode=bin

The available `site` parameters are listed and described in the following.

**Table 5.1. site parameters**

</table>

AUTOMOUNT=YES|NO|IMMED

If set to YES and a normal allocation fails because a data set is not online, Tectia will allocate it and request the system to mount it. This requires that the user has read permission to the `SSZ.MOUNT` facility.

If set to NO, offline data sets are not mounted automatically.

If set to IMMED, Tectia will not attempt the normal allocation, it will request the system to mount the data set immediately.

Default: NO

[NO]AUTOMOUNT | [NO]AUTOM

AUTOMOUNT | AUTOM is equal to AUTOMOUNT=YES.
NOAUTOMOUNT | NOAUTOM is equal to AUTOMOUNT=NO.

AUTORECALL=| NO

Defines whether data sets migrated by a storage manager are recalled automatically.

Default: YES

[NO]AUTORECALL | [NO]AUTOR

AUTORECALL | AUTOR is equal to AUTORECALL=YES.
NOAUTORECALL | NOAUTOR is equal to AUTORECALL=NO.

BLKSIZE|B|BLOCKSI=size

Specifies the maximum block size.

Default: none

BLOCKS|BL

Specifies that the space allocation unit is blocks. Equal to SPACE_UNIT=BLKS.

CONDDISP|CO=CATLG|UNCATLG|KEEP|DELETE

Specifies the disposition of the output file when a file transfer ends prematurely (the client or server are alive but disconnected from the other end; for example, when pressing CTRL+C in the client).

Note

If the client (when transferring to local or client side) or the server (when transferring to remote or server side) dies, they will have no control over the disposition.

The options have the following effects, depending on the file type (MVS or HFS):

- CATLG: an MVS data set is retained and its name is cataloged. An HFS file is retained.

- UNCATLG: the name of an MVS data set is removed from the catalog but the data set is retained. An HFS file is retained.

- KEEP: an MVS data set is retained (if cataloged it will be still cataloged, if uncataloged it will be still uncataloged). An HFS file is retained.

- DELETE: the name of an MVS data set is removed from the catalog and the space allocated for the data set is released. An HFS file is deleted.

Default: CATLG

CYLINDERS|CY

Specifies that the space allocation unit is cylinders. Equal to SPACE_UNIT=CYLS.
DATACLAS|DA=class

Specifies the data class of a data set.

Default: none

DATASET_SEQUENCE_NUMBER|SEQNUM=number

Identifies the relative position of a data set on a tape volume.

Default: System default

DEFER|DE=YES|NO

Specifies whether data set allocation is postponed from allocation phase to when the data set is opened.

If set to YES data set allocation is postponed until data set is opened.

If set to NO data set is allocated in allocation phase.

Default: NO

[NO]DEFER|DE

DEFER|DE is equal to DEFER=YES.

NODEFER is equal to DEFER=NO.

DIRECTORY_SIZE|M|DI|DIRSZ=size

Specifies the number of 256-byte records in the directory.

Default: 10

EXPIRY_DATE|EXPDT=yyddd|yyyyddd

Specifies the expiration date for a new data set. On and after this date, the operating system can delete or write over the data set.

Default: System default

FILE_STATUS|STATUS=NEW|MOD|SHR|OLD

Defines the status of a data set. If entered, the value will be used when allocating the data set. This attribute corresponds to the first value in the DISP parameter of the JCL DD statement. Possible values are:

- NEW: Create a data set.

- MOD: Append to an existing data set. If the data set does not exist, a new data set is created.

- SHR: Create a read-only data set.
OLD: Designate an existing data set.

FILETYPE|FILE=SEQ|JES

Specifies whether to interface with the file system or with the z/OS Job Entry Subsystem (JES).

Using FILETYPE=JES enables the commands **put** and **sput** to submit transferred files to the internal reader job queue for execution, and **get** and **sget** commands to retrieve spool data sets. To terminate interfacing with JES and return to normal file access, set the file type back to sequential (SEQ), or to an empty string (that is, FILETYPE=). Entering an empty string as file type sets the file type to default.

Default: SEQ

FIXRECFM|FI=length

The data set organization is set to FB and the fixed record length is set to length.

Default: none

JOB_ID|JESID=ID

When in FILETYPE=JES mode, JOB_ID specifies that commands accessing the JES spool, such as get, apply only to jobs with a job ID that matches the supplied ID.

Commands get, sget, and so on, with a job ID can be used to retrieve the spool files for a given job.

JOB_OWNER|JESO=name

When in FILETYPE=JES mode, JOB_OWNER specifies that commands accessing the JES spool, such as ls, and get, and so on, apply only to jobs with owner matching the supplied name.

Default: Current user

JOBNAME|JESJOB=name

When in FILETYPE=JES mode, JOBNAME specifies that commands accessing the JES spool, such as ls, get, and so on, apply only to jobs with job name matching the supplied name.

KEYLEN|KEYL=length

Specifies the length in bytes of the keys used in the data set.

Default: none

KEYOFF|KEYO=offset

Specifies the key offset; the position of the first byte of the key in records of the specified VSAM data set.

Default: none
The type of the label for the data set. This attribute corresponds to the first value in the `LABEL` parameter of the JCL DD statement.

**Note**

It is recommended for sites to control the use of `BLP` and `NL` tape processing by restricting access to the appropriate resource, using RACF or an equivalent security product.

`LIKE=like`

Specifies the name of a model data set from which the `RECFM`, `BLKSIZE`, and `LRECL` attributes are to be copied. The name must be the full DSN of a cataloged data set and must be preceded with three underscores.

You must include the `TYPE` attribute when using `LIKE` unless you are creating a PS data set and the model is a PS data set.

Default: none

`LRECL|R|LR=length`

Maximum record length or fixed record length.

Default: 4096 for VSAM, 80 if data set organization is `F` or `FB`, otherwise 1024

`MGMTCLAS|MG=class`

Specifies the management class of a data set.

Default: none

`NORMDISP|NOR=CATLG|UNCATLG|KEEP|DELETE`

Specifies the data set disposition to be used after a file transfer that ends normally. This attribute corresponds to the second value in the `DISP` parameter of the JCL DD statement.

Default: `CATLG`

`PRIMARY_SPACE|PRI=space`

Primary space allocation for a data set.

Default: none

`PROFILE|P|PROF=profile`

The file transfer profile specifies the named profile used for the file transfer. The profile name is case-sensitive. With special profile name `P=%` no profiles are used. This also prevents profile matching based on file name.
Default: none

**RECFM** | O | REC=recfm

**RECFM** specifies the data set organization. The possible values are all valid combinations of the following letters:

<table>
<thead>
<tr>
<th>Letter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>Fixed</td>
</tr>
<tr>
<td>V</td>
<td>Variable</td>
</tr>
<tr>
<td>U</td>
<td>Undefined</td>
</tr>
<tr>
<td>B</td>
<td>Blocked</td>
</tr>
<tr>
<td>S</td>
<td>Spanned or standard</td>
</tr>
<tr>
<td>M</td>
<td>Machine line printer codes</td>
</tr>
<tr>
<td>A</td>
<td>ASA line printer codes</td>
</tr>
</tbody>
</table>

Default: VB

**RECORD_TRUNCATE** | U | TRUN=YES | NO

When a record truncation occurs while writing an MVS data set, the system will continue writing the data set if **RECORD_TRUNCATE** is set to YES; and the system will abort the transfer if **RECORD_TRUNCATE** is set to NO or omitted.

Record truncation will occur if the length of a transferred record (after code set and line delimiter conversion) is larger than the maximum record length of the data set. Truncation can occur only when **TRANSFER_FORMAT** is set to LINE or RECORD. Note that the **STREAM** format does not have any concept of records in transferred data and it will fill out all records to their maximum length.

In the **LINE** transfer format, the length of a transferred record is the number of characters up to a newline character.

In the **RECORD** format, the length of a transferred record is given by the 4 byte binary length field which precedes the record.

The maximum length of a data set record depends on the data set organization:

<table>
<thead>
<tr>
<th>Data Set Organization</th>
<th>Maximum Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>F and FB</td>
<td>LRECL</td>
</tr>
<tr>
<td>V and VB</td>
<td>LRECL-4</td>
</tr>
<tr>
<td>U</td>
<td>BLKSIZE</td>
</tr>
<tr>
<td>VSAM</td>
<td>MAXRECLEN</td>
</tr>
</tbody>
</table>

When Tectia Client aborts writing a data set because of record truncation, it will complete the write operation during which the system observed the truncation. It will write to disk one or more records, at least one of which is truncated. The data set is left on the system.

Tectia Client may write a large amount of data in one write operation, typically 32kB. Several records may be written in the last operation, some of them truncated. Small files may be written to the end of the file, and thus the resulting data set will be equivalent to one written with setting **RECORD_TRUNCATE=**YES.

Note that some file transfer client programs do not always show the error or warning messages from the server. Using the verbose mode (**--verbose, -v**) may show more messages from the server.
Note

When Tectia Client writes a data set with RECORD_TRUNCATE=YES, data loss may occur.

[NO]TRUNCATE | [NO]TRU | [NO]TRUN

TRUNCATE | TRU | TRUN is equal to RECORD_TRUNCATE=YES.
[NO]TRUNCATE | [NO]TRU | [NO]TRUN is equal to RECORD_TRUNCATE=NO.

RETENTION_PERIOD | RET=days

The retention period in days. After the retention period, the data set expires and the operating system can delete or overwrite the data set.

Default: System default

SECONDARY_SPACE | SE | SEC=space

Secondary space allocation for a data set.

Default: none

SIZE | L=size

Size estimate (in bytes) for data set allocation.

Default: 1000000

SPACE_RELEASE | RLSE=YES | NO

When a new data set is allocated, SPACE_RELEASE specifies whether unused disk space will be released. If set to YES, unused disk space of a new data set is released. If set to NO, allocated disk space of a new data set is retained.

Default: YES

SPACE_UNIT | SU=BLKS | TRKS | CYLS | AVGRECLEN

Unit of space allocation for a data set.

Possible values for the space allocation unit are:

• BLKS: Blocks
• CYLS: Cylinders
• TRKS: Tracks
• AVGRECLEN: Average record length

Default: none

SPACE_UNIT_LENGTH | SUL=length

When SPACE_UNIT=BLKS or SPACE_UNIT=AVGRECLEN, specifies the size of the space allocation unit.
Default: 100 with SPACE_UNIT=AVGRECLEN, none with SPACE_UNIT=BLKS

STAGING|STAGE=YES|NO

Specifies whether staging is to be used in the SFTP server when accessing a file or data set.

If set to NO, staging is not used.

If set to YES, staging is used, when needed.

Default: NO

**Note**

When staging is used, do not set the `_CEE_RUNOPTS` environment variable's TRAP option to OFF. If you do, `sftpg3` fails to start. The TRAP option is ON by default.

STORCLAS|ST=class

Specifies the storage class of system managed storage.

Default: none

SVC99_TEXT_UNITS|SVC99=string

Dynamic allocation arguments that override or are added to arguments from other file transfer attributes.

Default: none

TRACKS|TR

Specifies that the space allocation unit is tracks. Equal to SPACE_UNIT=TRKS.

TRAILING_BLANKS|TRAIL=YES|NO

Specifies whether to preserve trailing blanks in a transferred data set.

If set to YES, trailing blanks will be transferred. This can be used, for example, to preserve the structure of fixed format data sets when transferring to a Unix-type file system.

If set to NO, trailing blanks will be stripped.

Default: NO

**Note**

This option only applies to line-delimited target files (TRANSFER_FORMAT=LINE), not to target unit-record data sets.

[NO]TRAILINGBLANKS| [NO]TRAI| [NO]TRAIL

TRAILINGBLANKS|TRAI|TRAIL is equal to TRAILING_BLANKS=YES.

NOTRAILINGBLANKS|NOTRAI|NOTRAIL is equal to TRAILING_BLANKS=NO.
TRANSFER_CODESET|C|CODESET=code\textit{set}

During the transfer the data has the specified code set. \textit{code\textit{set}} is the code set name that is known to the \texttt{iconv} function of the system performing the conversion. The available code sets can be listed by invoking the \texttt{iconv} command at a USS prompt with the \texttt{-l} option:

\begin{verbatim}
> iconv -l
\end{verbatim}

Default: none

Example: A Windows SFTP client puts a file to a z/OS data set and gets a data set from z/OS

\begin{verbatim}
sftp> site C=ISO8859-1 D=IBM-1047 \\
sftp> sput file.txt //DATASET.TXT \\
sftp> sget //DATASET.TXT file.txt
\end{verbatim}

\begin{enumerate}
\item The z/OS server is told that the code set during transfer is ISO8859-1 and that the data set is stored on the server with the IBM-1047 code set.
\item The server converts the code set from ISO8859-1 to IBM-1047 upon receiving the data.
\item The server converts the code set from IBM-1047 to ISO8859-1 before sending the data.
\end{enumerate}

\begin{itemize}
\item The line delimiter information is always given to the host that is capable of performing the conversion, in these cases the z/OS host.
\end{itemize}

TRANSFER_FILE_CODESET|D|FCODESET=code\textit{set}

The data in the data set has the specified code set. \textit{code\textit{set}} is the code set name that is known to the \texttt{iconv} function of the system performing the conversion. The available code sets can be listed by invoking the \texttt{iconv} command at a USS prompt with the \texttt{-l} option:

\begin{verbatim}
> iconv -l
\end{verbatim}

Default: none

TRANSFER_FILE_LINE_DELIMITER|J|FLDELIM=UNIX|MVS|MVS-FTP|DOS|MAC|NEL

The transfer file line delimiter specifies the newline convention used in the (source or destination) file. Possible values are:

\begin{itemize}
\item \texttt{UNIX}: The line delimiter used in the file is LF (\texttt{\textbackslash n}, \texttt{0x0A}).
\item \texttt{MVS}: The line delimiter used in the file is NL (\texttt{\textbackslash n}, \texttt{0x15}). When writing to a data set, also the CR (\texttt{\textbackslash r}, \texttt{0x0D}) code is considered as the End of Line.
\item \texttt{MVS-FTP}: When reading MVS data sets, each record in the data set is treated as a line. The transfer line delimiter is appended to the record. Any control characters in the record data are preserved.
\end{itemize}

When reading data sets with printer control characters, the control characters are preserved in the output.
If the code set conversion is specified either by `TRANSFER_TRANSLATE_TABLE|E`, or by `TRANSFER_CODESET|C` and `TRANSFER_FILE_CODESET|D`, the appended delimiter is the delimiter specified by `TRANSFER_LINE_DELIMITER|I`, `TRANSFER_CODESET|C`, or `TRANSFER_TRANSLATE_TABLE|E`. If no code set conversion is requested, the delimiter is defined by the code set of the data set. By default it is EBCDIC.

You can specify code sets by defining `TRANSFER_FILE_CODESET` without `TRANSFER_CODESET`. For example, to have a DOS delimiter in Unicode (`\x'0000000A'`) appended to the records, set "I=DOS,J=MVS-FTP,D=UCS-2", and to have a Unix delimiter in ISO Latin 1 (`\x'0A'`), set "I=UNIX,J=MVS-FTP,D=ISO8859-1".

Do not use this when writing data sets.

- **DOS**: The line delimiter used in the file is CRLF (`\r\n`, `0x0D 0x0A`).
- **MAC**: The line delimiter used in the file is CR (`\r`, `0x0D`).
- **NEL**: The line delimiter used in the file is Unicode New Line (`0x85`).

Default: none

**Note**

The line delimiter information should be given to the host that is capable of performing the conversion, such as a host with a Tectia.

Line delimiter conversion is implemented for single byte code sets only.

For the line delimiter conversion to happen, both `TRANSFER_LINE_DELIMITER|I` and `TRANSFER_FILE_LINE_DELIMITER|J` must be specified.

**Example: a z/OS Tectia SFTP client sends a data set to a Windows host and copies the file back from Windows**

In this example, the code set is also converted.

```
sftp> lsit I=dos J=mvs

sftp> lsit C=IBM-437 D=IBM-1047

sftp> sput //DATASET.TXT file.txt

sftp> sget file.txt //DATASET.COPY.TXT
```

1. Transfer line delimiter is set to DOS and transfer file line delimiter to MVS.
2. Transfer code set is set to IBM-437 and transfer file code set to IBM-1047.
3. The z/OS client inserts a NL (\x15) character after each record. The line delimiter conversion converts all NL:s to CRLF (\x0D 0x0A) characters, which remain unchanged in the code set conversion.
4. The CRLF line delimiters are converted to LF characters, which are converted to NL characters in the code set conversion. Each NL character (and CR character, if there are any in the data) causes the current record to be written out and a new record started.
The byte stream consists of the bytes that are transferred as payload in the SFTP protocol packets. The byte stream has one of the following formats: LINE, STREAM or RECORD. All three formats may have data consisting of text, non-text data, or a mixture of these.

When writing an MVS data set, a record that is longer than the maximum or fixed record length will cause an error unless RECORD_TRUNCATE is set to YES, in which case the record will be truncated. When writing to data sets with fixed record lengths, short records will be filled with binary zeroes if you use the record transfer format and with blanks if you use the line transfer format.

- **LINE**: The line transfer format is record-based. It uses delimiter characters to mark the end of a record. The delimiter character may be a Carriage Return (CR) or a Newline (NL). When writing to or reading from data sets with ASA control characters, a Form Feed (FF) is also treated as a delimiter. The table below shows the values of these characters in EBCDIC and ASCII. Data sent to Tectia Client in the line transfer format must be in EBCDIC or must be converted to EBCDIC during the transfer.

<table>
<thead>
<tr>
<th>Delimiter</th>
<th>EBCDIC</th>
<th>ASCII</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR Carriage Return</td>
<td>13 015 0x0D</td>
<td>CR 13 015 0x0D</td>
</tr>
<tr>
<td>NL Newline</td>
<td>21 025 0x15</td>
<td>LF 10 012 0x0A</td>
</tr>
<tr>
<td>FF Form Feed</td>
<td>12 014 0x0C</td>
<td>FF 12 014 0x0C</td>
</tr>
</tbody>
</table>

Note that ASCII does not have a NL character, instead Line Feed (LF) is used to delimit lines.

Avoid conversions that transform an ASCII Line Feed (LF/10/012/0x0A) into an EBCDIC Line Feed (LF/37/045/0x25) or an EBCDIC Newline (NL/21/025/0x15) into an ASCII Next Line (NEL/133/0205/0x85).

Be aware that sending a double delimiter, e.g. \r\n or \n\r, to Tectia Client will result in two records. The TRANSFER_LINE_DELIMITER and TRANSFER_FILE_LINE_DELIMITER attributes can be used to cause the Tectia Client server or client program to convert between the line delimiter conventions.

Tectia Client sends \n as the Server Newline Convention in the server initialization SFTP protocol message.

When transferring line format data to and from MVS files with ASA line printer control characters, Tectia Client will convert between the control characters and line delimiter characters, as described in the IBM z/OS XL C/C++ Programming Guide, Chapter “Using ASA Text Files”.

To transfer records without changing the ASA code, use the STREAM or RECORD transfer format, or define the data set using a DD card and specify RECFM=FB or RECFM=VB.

Data sets transferred in the line transfer format and recreated on a mainframe will not necessarily be identical.

- **STREAM**: The stream transfer format contains the data bytes of the data set but no structural information. If a data set with a fixed record length is transferred with the stream format and
recreated with the same record length, the record structure will be preserved. Variable length records will not be recreated properly if transferred with the stream format.

- **RECORD:** The record transfer format is record-based. Each record is preceded by a length field consisting of a 4-byte big-endian binary integer, which indicates the number of data bytes in the record. Note that the format is not the same as the record descriptor word in data sets with `RECFM=V` or `RECFM=VB`.

A data set that is transferred with the record transfer format can be recreated as any data set type.

Default: `LINE`.

```plaintext
TRANSFER_LINE_DELIMITER I LDELIM=UNIX | MVS | MVS-FTP | DOS | MAC | NEL
```

The transfer line delimiter specifies the newline convention used in the data that is transferred over the connection. Possible values are:

- **UNIX:** The line delimiter on the connection is LF (`\n`, `0x0A`).

- **MVS:** The line delimiter on the connection is NL (`\n`, `0x15`). If the data is converted from EBCDIC to ASCII, the NL becomes a LF (`\n`, `0x0A`).

- **MVS-FTP:** When writing to a data set, only the LF (`\n`, `0x0A`) control codes are considered as an End Of Line. Any CR (`\r`, `0x0D`) codes are preserved as data in the record.

  When writing data sets with ASA printer control characters, the first character on each line is used as the ASA character.

  Do not use this when reading data sets.

- **DOS:** The line delimiter on the connection is CRLF (`\r\n`, `0x0D 0x0A`).

- **MAC:** The line delimiter on the connection is CR (`\r`, `0x0D`).

- **NEL:** The line delimiter used in the file is Unicode New Line (`0x85`).

Default: `none`

**Note**

The line delimiter information should be given to the host that is capable of performing the conversion, such as a host with a Tectia.

```plaintext
TRANSFER_MODE X MODE=BIN | TEXT
```

The transfer mode specifies whether code set and line delimiter conversions are performed. The available values are:

- **BIN:** Code set and line delimiter conversions are not performed.

- **TEXT:** Code set and line delimiter conversions are performed.
Default: none

Note

If TRANSFER_MODE is not given but both TRANSFER_CODESET and TRANSFER_FILE_CODESET or TRANSFER_TRANSLATE_TABLE are present conversions are performed.

TRANSFER_TRANSLATE DSN_TEMPLATES | A| XDSNT=templates

templates specifies the search templates for the translate table. Write '%%T' to show the point where the translate table name (see above) is to be inserted. Delimit the templates with a plus character. The data set name templates must not contain slashes, instead they must be preceded by two or three underscores.

The first translate table data set that is found is used to perform the code conversion.

Note

The translate table must translate line delimiters into EBCDIC NL characters. See TRANSFER_FORMAT.

Default: none

TRANSFER_TRANSLATE TABLE | E| X TBL=table

TABLE is the name of the table that specifies the code set conversion. If set, this attribute overrides the transfer code set and file code set attributes. The table is always applied in the normal direction, that is, the first character array is used for incoming (from the line to the data set) data and the second array for outgoing data. If the opposite translation is needed, e.g. the data set contains ASCII and should be transferred as EBCDIC, you (or your system programmer) can prepare a table data set with the character arrays in reversed order (e.g. with the system utility CONVXLAT or by editing an existing translate data set).

TYPE | T=PS| PO| PDS| POE| PDSE| GDG| HFS| VSAM| ESDS| KSDS| RRN

Specifies the type of a data set when the data set is created. The available values are:

• PS: The type of the created data set is PS.

• PO|PDS: The type of the created data set should be PDS. Note that in order to create a PDS, you need to specify the DIRECTORY_SIZE parameter. If you do not specify the directory size, a sequential data set - not a partitioned data set - is created.

• POE|PDSE: The type of the created data set is PDSE.

• GDG: The type of the created data set is GDG.

• HFS: The type of the created data set is HFS.

• VSAM: The type of the created data set is VSAM.
• **ESDS**: The type of the created data set is VSAM ESDS.

• **KSDS**: The type of the created data set is VSAM KSDS.

• **RRN**: The type of the created data set is VSAM RRN.

**Default**: PO, if data set name includes member, otherwise PS

**UNIT** | **UN=unit**

The name of the device or group of devices that the data set will reside on (or does reside on, if it already exists). The maximum length of *unit* is 8 characters. If the value exceeds the maximum length, it is truncated to 8 characters.

It is also possible to specify a device address. Precede a four digit address with an underscore.

**Default**: none

**UNIT_COUNT** | **UC** | **UNC=number**

Specifies the number of devices for the data set. This attribute corresponds to the second value in the **UNIT** parameter of the JCL DD statement.

**Default**: System default

**UNIT_PARALLEL** | **UNP=YES** | **NO**

Asks the system to mount all the volumes for the data set in parallel. This attribute corresponds to the character ‘p’ in the second value in the **UNIT** parameter of the JCL DD statement.

**Default**: System default

**VOLUME_COUNT** | **VC** | **VOLCNT=number**

Specifies the maximum number of volumes that an output data set requires. This attribute corresponds to the volume count value in the **VOLUME** parameter of the JCL DD statement.

**Default**: System default

**VOLUMES** | **VO** | **VOL=vol1+vol2+...**

A plus sign (+) separated list of volumes a data set will reside on (or does reside on, if it already exists).

**Default**: none
Chapter 6 Secure Shell Tunneling

Tunneling is a way to forward otherwise unsecured application traffic through Secure Shell. Tunneling can provide secure application connectivity, for example, to POP3, SMTP, and HTTP-based applications that would otherwise be unsecured.

The Secure Shell v2 connection protocol provides channels that can be used for a wide range of purposes. All of these channels are multiplexed into a single encrypted tunnel and can be used for tunneling (forwarding) arbitrary TCP/IP ports and X11 connections.

The client-server applications using the tunnel will carry out their own authentication procedures, if any, the same way they would without the encrypted tunnel.

The protocol/application might only be able to connect to a fixed port number (e.g. IMAP 143). Otherwise any available port can be chosen for tunneling. For remote tunnels, the ports under 1024 (the well-known service ports) are not allowed for ordinary users, but are available only for system administrators (root privileges).

There are two basic kinds of tunnels: local and remote. They are also called outgoing and incoming tunnels, respectively. X11 forwarding and agent forwarding are special cases of a remote tunnel. The different tunneling options are handled in the following sections.

6.1 Local Tunnels

A local (outgoing) tunnel forwards traffic coming to a local port to a specified remote port.

With sshg3 on the command line, the syntax of the local tunneling command is as follows:

```
client$ sshg3 -L [protocol/][listen-address:][listen-port]:dst-host:dst-port sshserver
```

where:

- `[protocol/]` specifies which protocol is to be used in the tunneled connection, it can be ftp or tcp (optional argument). The default is tcp.

- `[listen-address:]` defines which interface on the local client will be listened to (optional argument). By default all interfaces are listened.
• listen-port is the number of the port on the local client, and connections coming to this port will be tunneled to the server.

• dst-host:dst-port define the destination host address and the port to which the connection is tunneled from the server.

• sshserver is the IP address or the host name of the Secure Shell server.

The host name or IP address of the destination host and sshserver can be defined as regular expressions that follow the egrep syntax, but no wildcards are supported.

**Note**

If dst-host is specified as a domain name rather than IP address, the name will be resolved according to the address family settings of sshserver. For example, if the domain name is resolved to an AAAA DNS record (IPv6) and the address family setting of the server is inet (IPV4), the tunnel will not work.

Setting up local tunneling allocates a listener port on the local client host. Whenever a connection is made to this listener, the connection is tunneled over Secure Shell to the remote server and another connection is made from the server to a specified destination host and port. The connection from the server onwards will not be secure, it is a normal TCP connection.

**Note**

Every user with access to the local client host will be able to use the local tunnels.

Figure 6.1 shows the different hosts and ports involved in local tunneling (port forwarding).

**Figure 6.1. Local tunneling terminology**

For example, when you issue the following sshg3 command on the command line, all traffic coming to port 1234 on the client host will be forwarded to port 23 on the server.

```
client$ sshg3 -L 1234:localhost:23 --abort-on-failing-tunnel username@sshserver
```

The forwarding address in the command is resolved at the (remote) end point of the tunnel. In this case localhost refers to the server host (sshserver).
In this example, also the `--abort-on-failing-tunnel` option is specified. It causes the command to abort if creating the tunnel listener fails (for example, if the port is already reserved). Normally if the connection to the server succeeds, but creating the listener fails, no error message is given.

### 6.1.1 Non-Transparent TCP Tunneling

When non-transparent TCP tunneling is used, the application to be tunneled is set to connect to the local listener port instead of connecting to the server directly. Tectia Client forwards the connection securely to the remote server.

![Figure 6.2. Simple local tunnel](image)

If you have three hosts, for example, `sshclient`, `sshserver`, and `imaps-server`, and you forward the traffic coming to the `sshclient`'s port 143 to the `imaps-server`'s port 143, only the connection between the `sshclient` and `sshserver` will be secured. The command you use would be similar to the following one:

```bash
sshclient$ sshg3 -L 143:imaps-server:143 username@sshserver
```

*Figure 6.3* shows an example where the Secure Shell server resides in the DMZ network. Connection is encrypted from the Secure Shell client to the Secure Shell server and continues unencrypted in the corporate network to the IMAP server.

![Figure 6.3. Local tunnel to an IMAP server](image)

Tunnels can also be defined for connection profiles in the Connection Broker configuration file. The defined tunnels are opened automatically when a connection with the profile is made. The following is an example from a `ssh-broker-config.xml` file:

```xml
<profile id="id1" host="sshserver.example.com">
```

© 1995–2021 SSH Communications Security Corporation
...<tunnels>
  <local-tunnel type="tcp"
    listen-port="143"
    dst-host="imap.example.com"
    dst-port="143"
    allow-relay="no" />
...</tunnels></profile>

By default, local tunnels originating only from the client host itself are allowed. To allow also other machines to connect to the tunnel listener port, set the allow-relay to yes.

The tunneling settings can be made in the Tectia Connections Configuration GUI, under **Connection Profiles → Tunneling** per each profile. See the section called “Defining Tunneling”.

**Automatic Tunnels**

Automatic tunnels are one way of creating non-transparent local tunnels for application connections.

Automatic tunnels always use a connection profile in the tunnel establishing. You can create listeners for local tunnels that will be activated automatically when the Connection Broker starts up. The actual tunnel will be formed the first time a connection is made to the listener port. If the connection to the server is not open at that time, it will be opened automatically as well.

In the Connection Broker configuration file, make the following kind of settings:

<static-tunnels>
  <tunnel type="tcp"
    listen-port="9874"
    dst-host="st.example.com"
    dst-port="9111"
    allow-relay = "no"
    profile="id1" />
</static-tunnels>

You can configure the automatic tunnels in the Tectia Connections Configuration GUI, on the **Automatic Tunnels** page. For instructions, see **Section A.1.6**.

**Examples of Local Tunneling**

When **sshg3** is used to create secure tunnels using local port forwarding, the TCP applications to be tunneled are configured to connect to a localhost port instead of the application server port.

**Example application**, **clientapp1**, by default connects to a Unix server **unix.example.com** using TCP port 2345.

```bash
$ clientapp1 --username user1 --server unix.example.com --port 2345
```

For securing this TCP application using Secure Shell, use the following commands:

```bash
$ sshg3 -L 2345:localhost:2345 user1@unix.example.com -S -f &
```
Non-Transparent FTP Tunneling

The above `sshg3` command connects to remote Secure Shell server `unix.example.com`, creates a local listener on port 2345, instructs the remote Secure Shell server to forward the incoming traffic to `localhost:2345`, and goes to background in single-shot-mode.

6.1.2 Non-Transparent FTP Tunneling

Non-transparent FTP tunneling is an extension to the generic tunneling mechanism. Unlike generic tunneling (port forwarding) mechanism, non-transparent FTP tunneling secures the transferred files, in addition to the FTP control channel. The FTP tunneling code monitors the tunneled FTP control channels and dynamically creates new tunnels for the data channels as they are requested.

When non-transparent FTP tunneling is used, tunnels are created from local client ports to remote servers. The FTP client is configured to connect to Tectia Client which will forward the connection to the endpoint where a Secure Shell server is running.

The typical use case is that Tectia Client is located on the same host as the FTP client; and the FTP server is on the same host as the Secure Shell server. However, other configurations are also supported, but it is worth noticing that the connection is encrypted only between Tectia Client and the Secure Shell server.

Non-transparent FTP tunneling can be requested on the command line, or enabled and defined in the Connection Broker configuration. The configured non-transparent FTP tunneling uses connection profiles, that are defined on Tectia Client.

On command-line, FTP tunneling can be used for both local and remote tunnels. Non-transparent FTP-tunneling is started by entering a `sshg3` command with the following syntax:

```
sshclient$ sshg3 -L ftp/1234:localhost:21 username@sshserver
```

For information on the `sshg3` command, see the `sshg3(1)` man page.

The FTP tunneling settings can be made in the Tectia Connections Configuration GUI, under Connection Profiles → Tunneling for each profile. See the section called “Defining Tunneling”.

FTP tunnels can also be defined for connection profiles in the Connection Broker configuration file. The following is an example from the Connection Broker configuration file `ssh-broker-config.xml`:

```xml
<profiles>
  <profile id="id1" host="sshserver.example.com"
    ...
    <tunnels>
      <local-tunnel type="FTP"
        listen-port="1234"
        dst-host="127.0.0.1"
        dst-port="21"
        allow-relay="NO" />
      ...
    </tunnels>
  </profile>
</profiles>
```
An FTP connection can then be made with the following (example) commands:

```
sshclient$ ftp
ftp$ open localhost 1234
```

The FTP connection to port 1234 on client is now tunneled to port 21 on the Secure Shell server.

As an alternative to FTP tunneling, you can use the `sftpg3` or `scpg3` clients for secure file transfers. These clients can be used on command line or in scripts and they require less configuration than FTP tunneling, since Tectia Server already has `sft-server-g3` as a subsystem, and `sftpg3` and `scpg3` clients are included with Tectia Client. Managing remote user restrictions on the server machine will be easier, since you do not have to do it also for FTP.

To understand exactly how FTP tunneling is done, two different cases need to be examined: the active mode and the passive mode of the FTP protocol.

**Tunneling FTP in Passive Mode**

In passive mode, the FTP client sends the command `PASV` to the server, which reacts by opening a listener port for the data channel and sending the IP address and port number of the listener as a reply to the client. The reply is of the form

```
227 Entering Passive Mode (a1,a2,a3,a4,p1,p2)
```

where `a1.a2.a3.a4` is the IP address and `p1*256+p2` is the port number. For example, the reply for IP address 10.1.60.99 and port 1548 is: 227 Entering Passive Mode (10,1,60,99,6,12).

When the Connection Broker notices the reply to the `PASV` command, it will create a local port forwarding to the destination mentioned in the reply. After this the Connection Broker will rewrite the IP address and port in the reply to point to the listener of the newly created local port forwarding (which exists always in a localhost address, 127.0.0.1) and pass the reply to the FTP client. The FTP client will open a data channel based on the reply, effectively tunneling the data through the Secure Shell connection, to the listener the FTP server has opened. The net effect is that the data channel is secured all the way except from the Secure Shell server to the FTP server if they are on different machines. This sequence of events takes place automatically for every data channel.

Since the tunnel is opened to a localhost address, the FTP client must run on the same machine as Tectia Client if passive mode is used.

**Tunneling FTP in Active Mode**

In active mode, the FTP client creates a listener on a local port, for a data channel from the FTP server to the FTP client, and requests the channel by sending the IP address and the port number to the FTP server in a command of the following form:

```
PORT a1,a2,a3,a4,p1,p2
```

where `a1.a2.a3.a4` is the IP address and `p1*256+p2` is the port number. The Connection Broker intercepts this command and creates a remote port forwarding from the localhost address of the Secure Shell server to the address and port specified in the `PORT` command.
After creating the tunnel, the Connection Broker rewrites the address and port in the `PORT` command to point to the newly opened remote forwarding on the Secure Shell server and sends it to the FTP server. Now the FTP server will open a data channel to the address and port in the `PORT` command, effectively forwarding the data through the Secure Shell connection. The Connection Broker passes the incoming data to the original listener created by the FTP client. The net effect is that the data channel is secure the whole way except from Tectia Client to the FTP client. This sequence of events takes place automatically for every data channel.

For FTP tunneling in active mode to work, the FTP server must be run on the same host as the Secure Shell server, and the FTP client and Tectia Client must reside on the same host.

**Note**

Tunneling FTP in active mode is not guaranteed to work in all setups. If possible, use the passive mode when tunneling FTP connections.

### 6.1.3 SOCKS Tunneling

SOCKS tunneling is a mechanism available for tunneling applications that support the SOCKS4 or SOCKS5 client protocol.

Instead of configuring tunneling (a.k.a port forwarding) from specific ports on the local host to specific ports on the remote server, you can specify a SOCKS server which can be used by the user's applications. Each application is configured in the regular way except that it is configured to use a SOCKS server on a localhost port. The Secure Shell client application, Tectia Client, opens a port in the localhost and mimics a SOCKS4 and SOCKS5 server for any SOCKS client applications.

When the applications connect to services such as IMAP4, POP3, SMTP, and HTTP, they provide the necessary information to the SOCKS server, which is actually Tectia Client mimicking a SOCKS server. Tectia Client will use this information in creating a tunnel to the Secure Shell server and relaying the traffic back and forth securely.

With `sshg3` on the command line, the syntax of the SOCKS tunneling command is as follows:

```bash
client$ sshg3 -L socks/[listen-address:]listen-port username@sshserver
```

where:

- `[listen-address:]` defines which interface on the client will be listened to (optional argument)
- `listen-port` is the number of the port on the client
- `sshserver` is the IP address or the host name of the Secure Shell server.

For example, the following command will set up a local tunnel from port 1234 on the client to `sshserver`. The applications are set to use a SOCKS server at port 1234 on the client. From the server, the connections are forwarded unsecured to the destination hosts requested by the applications.

```bash
sshclient$ sshg3 -L socks/1234 username@sshserver
```
SOCKS tunnels can also be defined for connection profiles in the Connection Broker configuration file. The following is an example from a `ssh-broker-config.xml` file:

```xml
<profile id="id1" host="sshserver.example.com">
  ...
  <tunnels>
    <local-tunnel type="socks"
      listen-port="1234"
      allow-relay="no" />
    ...
  </tunnels>
</profile>
```

### 6.2 Remote Tunnels

A remote (incoming) tunnel forwards traffic coming to a remote port to a specified local port.

With `sshg3` on the command line, the syntax of the remote tunneling command is as follows:

```bash
client$ sshg3 -R [protocol/]\[listen-address:][listen-port:]dst-host:dst-port \
username@sshserver
```

where:

- `[protocol/]` specifies which protocol is to be used in the tunneled connection, it can be `ftp` or `tcp` (optional argument). The default is `tcp`.

- `[listen-address:]` defines which interface on the remote server will be listened to (optional argument). By default all interfaces are listened.

- `listen-port` is the number of the port on the remote server, and connections coming to this port will be tunneled to the client.

- `dst-host:dst-port` define the destination host address and the port to which the connection is tunneled from the client.

- `sshserver` is the IP address or the host name of the Secure Shell server.

The IP addresses and host names of the destination host and the `sshserver` can be defined using regular expressions that follow the `egrep` syntax. No wildcards are supported.

**Note**

If `dst-host` is specified as a domain name rather than IP address, the name will be resolved according to the address family settings of `client`. For example, if the domain name is resolved to an `AAAA` DNS record (IPv6) and the address family setting of the client is `inet` (IPV4), the tunnel will not work.

Setting up remote tunneling allocates a listener port on the remote server. Whenever a connection is made to this listener, the connection is tunneled over Secure Shell to the local client and another connection is
made from the client to a specified destination host and port. The connection from the client onwards will not be secure, it is a normal TCP connection.

**Note**

Every user with access to the remote server host will be able to use remote tunnel.

Figure 6.4 shows the different hosts and ports involved in remote port forwarding.

![Figure 6.4. Remote tunneling terminology](image)

**Figure 6.4. Remote tunneling terminology**

For example, if you issue the following command, all traffic which comes to port 1234 on the server will be tunneled to port 23 on the client. See Figure 6.5.

```bash
ssh-client$ sshg3 -R 1234:localhost:23 username@sshserver
```

The forwarding address in the command is resolved at the (local) end point of the tunnel. In this case `localhost` refers to the client host.

![Figure 6.5. Remote tunnel](image)

**Figure 6.5. Remote tunnel**

Tunnels can also be defined for connection profiles in the Connection Broker configuration file. The defined tunnels are opened automatically when a connection with the profile is made.

The following is an example from a `ssh-broker-config.xml` file:

```xml
<profile id="id1" host="sshserver.example.com">
  ...
  <tunnels>
    <remote-tunnel type="tcp"
      listen-port="1234"
  </remote-tunnel>
```

© 1995–2021 SSH Communications Security Corporation
6.3 X11 Forwarding

X11 forwarding is a special case of remote tunneling.

Tectia Client supports X11 forwarding on both Unix and Windows platforms. On Windows, you need also the XWindow Manager package. Tectia Server supports X11 forwarding only on Unix platforms.

![Diagram of X11 forwarding](image)

**Figure 6.6. X11 forwarding**

X11 forwarding can be enabled in the client by setting the following line in the `ssh-broker-config.xml` file (either under default-settings or under a connection profile):

```xml
<forwards>
  <forward type="X11" state="on"/>
</forwards>
```

By default, X11 forwarding is off.

X11 forwarding can be enabled in the Tectia Connections Configuration GUI, under Default Connection → Tunneling for the default connection, and under Connection Profiles → Tunneling per each profile. See the section called “Defining Default Tunneling Settings” and the section called “Defining Tunneling”.

To test that X11 forwarding works on Windows, use the XWindow Manager. Log into the remote system and type `xclock &`. This starts an X clock program that can be used for testing the forwarding connection.

If the X clock window is displayed properly, you have the X11 forwarding working. If the X clock fails and complains that it cannot open the display, check that the XAuth is properly installed on the remote host.

**Note**

Do not set the `DISPLAY` variable on the client. You will most likely disable encryption. (X connections tunneled through Secure Shell use a special local display setting.)
6.4 Agent Forwarding

Agent forwarding is a special case of remote tunneling. In agent forwarding, Secure Shell connections and public-key authentication data are forwarded from one server to another without the user having to authenticate separately for each server. Authentication data does not have to be stored on any other machine than the local machine, and authentication passphrases or private keys never go over the network.

Tectia Client provides authentication agent functionality and the Connection Broker can also serve OpenSSH clients as an authentication agent. Tectia Server supports agent forwarding on Unix platforms. Thus, the start and end points of the agent forwarding chain can be Windows or Unix hosts, but all hosts in the middle of the forwarding chain must be Unix hosts and must have both the Secure Shell client and server components installed.

Figure 6.7. Agent forwarding

In the factory settings, agent forwarding is enabled (on).

Agent forwarding can be enabled or disabled on the client side both in the default configuration settings and separately for each connection profile.

In the `ssh-broker-config.xml` file, agent forwarding can be disabled by setting the following line either under `default-settings` or under a connection profile:

```xml
<forwards>
  <forward type="agent" state="off" />
</forwards>
```

Agent forwarding can be disabled in the Tectia Connections Configuration GUI, under Default Connection → Tunneling for the default connection, and under Connection Profiles → Tunneling per each profile. See the section called “Defining Default Tunneling Settings” and the section called “Defining Tunneling”.
Chapter 7 Troubleshooting Tectia Client

If you encounter any connection, authentication, or configuration problems, you can try to solve them by running Tectia Client in debug mode. For more information on debugging, see instructions in Section 7.3.

You can also gather information needed for troubleshooting and send it to SSH technical support. See Section 1.2 for information on accessing the Tectia online support resources and contacting SSH technical support.

The information you need to provide to SSH technical support includes:

- The verbose level output of Tectia Client; see Section 7.1.
- System information from Tectia Troubleshooting Tool's output. This information will help in analyzing the reported problems, as the technical support gets to know the exact details about the environment where the Tectia products are running; see Section 7.2.
- Possibly debug information; see Section 7.3.

7.1 Gathering Basic Troubleshooting Information

Most connection problems can be solved by running sshg3 in verbose mode and examining the output.

Enter the command -v (or --verbose) to get the diagnostic output:

$$\text{
sshg3 -v user@server.example.com
}$$

You can also get the diagnostic output from the old connection attempts afterwards. The following command lists the old connection attempts and their connection IDs:

$$\text{
ssh-broker-ctl list-connections --disconnected
}$$

The following command shows the diagnostic output from the old connection attempts:

$$\text{
ssh-broker-ctl connection-status <connection-id>
}$$

On Windows, the Tectia - SSH Terminal provides error dialog messages for failed connection attempts. Moreover, you can get the connection information and the last 5 messages displayed by the Tectia Client
Chapter 7 Troubleshooting Tectia Client

by opening the Tectia - SSH Terminal and selecting Help → Troubleshooting... A window like the one shown in Figure 7.1 is then opened.

Figure 7.1. Window containing troubleshooting data

7.2 Collecting System Information for Troubleshooting

Tectia Client includes a troubleshooting tool that automatically collects necessary data about the operating system and hardware, and about the installed Tectia product versions and their configurations into a file. The troubleshooting tool gathers the following information about the system configuration:

- The operating system (OS) version and patches installed
- OS configuration files and other OS information, for example, about PAM, syslog, resolver, and ifconfig
- Hardware information, for example, the machine model, security class, and CPU version
- OS status, for example, the reserved ports and connections per socket
- Tectia binaries, the tool checks the actual installation package versions and detects also debug packages
- Tectia global configuration from the /etc/ and /opt/ directories on Unix, and from the default installation directory on Windows:
  - "C:\Program Files\SSH Communications Security\SSH Tectia" on 32-bit Windows versions
  - "C:\Program Files (x86)\SSH Communications Security\SSH Tectia" on 64-bit Windows versions
- User-specific Tectia configuration from user's home directory: $HOME/.ssh2 on Unix, and "C:\Documents and Settings\<username>" or "C:\Users\" on Windows
• The user account running the troubleshooting tool

• On Unix, it is configurable if everything stored in the specified user's configuration directories, including the private keys, are to be collected. This helps the Technical Support to better simulate the user's situation.

To collect system information, open a command prompt and enter the following command:

On Unix, run the troubleshooting tool with command:

```
$ ssh-troubleshoot [options] info [command-options]
```

On Windows, run the troubleshooting tool with command:

```
ssh-troubleshoot.cmd [options] info
```

For details about the command options, refer to ssh-troubleshoot(8).

The collected data is stored in the results file named as follows:

• On Unix: `ssh-troubleshoot-data-<hostname>-<timestamp>.tar`

• On Windows: `ssh-troubleshoot-data-<hostname>-<timestamp>.log`

In the file name, `hostname` identifies the host from where the information was collected, and `timestamp` specifies the date and time when the information was stored into the file. The timestamp format is `yyyyymmdd-hhmmUTC`. So the reports are not in local time, but use the UTC.

You can send the file to SSH Technical Support for analysis.

⚠️ **Caution**

Handle the output file with appropriate care as it may contain security-critical data.

### 7.3 Setting Connection Broker to Debug Mode

The Connection Broker is a component included in Tectia Client. The Connection Broker handles all cryptographic operations and authentication-related tasks for Tectia Client and the command-line tools `sshg3`, `scpg3`, and `sftpg3`.

If the verbose level output explained in Section 7.1 does not solve your problem, set the existing running Broker to debug mode. Existing open connections will remain up and running, which is relevant on multiuser systems or when there are lots of automated scripts running at the same time. You will also get a debug log from new connection attempts.

To set the Connection Broker to debug mode, follow these instructions:

1. Open a shell (on Unix) or command prompt window (on Windows).

2. If you already have an existing Connection Broker, skip this step. If you do not have an existing Connection Broker, run the following command:
3. Set the Connection Broker to debug mode by running the following command:

```
$ ssh-broker-ctl debug --log-file=<logfile> <debug-level>
```

In the command:

- **logfile** specifies the file to which the debug output will be directed
- **debug-level** is an integer from 0 (no debug info) to 99 that specifies the desired amount of debug information.

**Note**

The recommended debug levels are 1-9. The higher the number, the more detailed the troubleshooting output will be, and the more the debugging will affect performance.

On Windows, you can set the debug mode also in the **Logs** view in the **Tectia Connection Status** window. To open the **Tectia Connection Status** window, right-click the **Tectia** icon in the Windows taskbar notification area and select **Status**.

![Figure 7.2. Setting the Connection Broker's debug mode on Windows](image)

The following example command sets the Connection Broker debug mode to level 4 and outputs the debug information to a log file named `broker.log`:

```
$ ssh-broker-ctl debug --log-file=broker.log 4
```

4. Connect to a server using one of the clients:

```
$ sshg3 user@host
```

5. View the debug information for the connection in the `broker.log` file.
On Unix, you can display the debug output also by using the command line tools with argument `-D`. For example, the following command will display the debug output with a debug level 2:

$ sftpg3 -D2 user@host

On Windows, besides the command line tools, you can display the debug output also in the Tectia Connection Status window.

Note

After you have collected the debug output, remember to disable Tectia Client's debug mode, since debugging slows down the performance.

On Unix and Windows, the debug mode is disabled with the following command:

$ ssh-broker-ctl debug --clear

On Windows, the debug mode can be also disabled by setting the debug level back to 0 in the Tectia Connection Status window, as shown in Figure 7.3

![Figure 7.3. Disabling the Connection Broker's debug mode on Windows](image)

7.4 Answers to Common Problems

This sections introduces workaround instructions for some problem situations.

Troubleshooting GSSAPI Authentication

When connecting from a Windows 5.x or 6.x client to a Windows 4.x server using GSSAPI authentication, if authentication fails although GSSAPI has been correctly configured, you may have to disable the LMHOSTS lookup on the client-side computer. Follow these instructions:
1. Select Control Panel → Network Connections.

2. In Local Area Connection, right-click and select Properties.

3. In the Local Area Connection Properties dialog box, General tab, select Internet Protocol (TCP/IP) and click the Properties button.

4. In the Internet Protocol (TCP/IP) Properties dialog box, in the General tab, click the Advanced button.

5. In the Advanced TCP/IP Settings dialog box, in the WINS tab, clear the Enable LMHOSTS lookup check box.

6. Restart the client-side computer.

**Password Window Loses Focus**

In some cases on Windows clients, the window for the password or the public-key passphrase can lose focus. This means that the password window is shown active on the screen, but when you start typing your password, the asterisks do not appear in the box. If the actual focus happens to be in another window, your password or passphrase may appear there.

The password window loses focus most often when you have the Tectia Connection Broker status window open. So the first workaround is to make sure the status window is not open while you start logging in.

A permanent solution to the problem is to modify the Windows settings that control the behaviour of the applications. By default, Windows has an option that prevents applications from stealing the focus. As a workaround, you can allow applications to steal the focus. Note that the setting affects all Windows applications, not just the Tectia Connection Broker.

To be able to change the setting, you need to download the Microsoft Tweak UI utility program. Follow these instructions:

2. Install the Tweak UI on your computer with the help of the installation wizard included.

3. Start the program from the Start menu.

4. Go to the General - Focus view and clear the Prevent applications from stealing focus check box as shown in the following figure.
Figure 7.4. Microsoft Tweak UI utility

5. Click **Apply** or **OK**.
Appendix A Connection Broker Configuration Tools

The Connection Broker is a component included in Tectia Client, and it handles all cryptographic operations and authentication-related tasks for Tectia Client. For this reason, all authentication and connection profile settings are made in the Connection Broker configuration.

The Connection Broker configuration can be edited and viewed via the Tectia Connections Configuration GUI. For instructions, see Section A.1.

The Connection Broker stores the settings in an XML-based configuration file `ssh-broker-config.xml`. It is possible to edit the configuration file directly with an ASCII-text editor or an XML editor. For a detailed description of the configuration file, see `ssh-broker-config(5)`. For a quick reference to the configuration file's elements and their attributes, see Section A.4.

A.1 Tectia Connections Configuration GUI

You can use the Tectia Connections Configuration GUI to edit the authentication and connection profile settings on the Connection Broker included in Tectia Client.

Tectia Connections Configuration GUI is available on Windows and Linux for Tectia Client. There are some differences in the GUI options between different OS platforms and product versions. The following screen shots typically show Tectia Client on Windows. When the differences are important, also screens from the Linux version are shown.
Figure A.1. Connection profile tabs on Linux
Figure A.2. Connection profile tabs on Windows

On Linux, the Tectia Connections Configuration GUI interface differs from the Windows version most notably with the following exceptions:

- The Windows, Colors, Terminal, File Transfer and Favorite Folders tabs of a connection profile are not available.

- The Microsoft Crypto API option on the Key Providers page is not available.

- The Linux GUI does not have the Help button for accessing the help contents.

Note

Only KDE and Gnome window managers are supported. For other compatible managers, check the website for the Qt framework.

A.1.1 Opening the GUI

Windows

On Windows, the Tectia Connections Configuration GUI can be accessed in several ways:
• Right-click on the Tectia tray icon in the Windows taskbar notification area to access the shortcut menu, and select Configuration.

• When you have the Tectia SSH Terminal GUI active, click the Tectia Connections Configuration GUI icon in the toolbar or select Edit → Tectia Connections in the menu bar.

On Windows, Tectia Client includes a separate GUI for configuring the user interface settings for the Tectia SSH Terminal GUI. Open the Settings tool by clicking the icon in the toolbar of the Tectia SSH Terminal GUI. For instructions on the GUI configurations, see Appendix B.

Linux

On Linux, the Tectia Connections Configuration GUI can be started by running:

```
$ /opt/tectia/bin/ssh-tectia-configuration
```

The following options are available:

- `-f, --config=FILE`
  
  Use configuration file FILE.

- `-a, --broker-address=ADDR`
  
  Connect to separate Connection Broker process using given address.

- `-d, --debug=STR`
  
  Sets debug string to STR.

- `--convert`
  
  Convert old configuration file.

- `--new-profile`
  
  Add a new profile.

- `--profile-host=HOST`
  
  Profile host name when adding a new profile.

- `--profile-port=PORT`
  
  Profile port when adding a new profile.

- `--profile-user=USER`
  
  Profile user when adding a new profile.
--edit-profile=NAME

Edit existing profile NAME.

--ui-mode=MODE

User interface mode. Possible values are standard and file-transfer.

-V, --version

Print version.

-h, --help

Print usage.

A.1.2 Defining General Settings

On the General page, you can select the cryptographic library to be used and define the Tectia tray icon settings.

![General settings](image)

Figure A.3. General settings

Configuration File

Shows the location of the user-specific Broker configuration file. The default location is "%APPDATA%\SSH\ssh-broker-config.xml" on Windows and "$HOME/.ssh2/ssh-broker-config.xml" on Linux.
Each time the configuration file is saved, a backup of the old configuration is stored in "%APPDATA%\SSH\ssh-broker-config.xml.bak" on Windows and "$HOME/.ssh2/ssh-broker-config.xml.bak" on Linux.

Cryptographic Library

Tectia Client can be operated in FIPS mode, using a version of the cryptographic library that has been validated according to the Federal Information Processing Standard (FIPS) 140-2. In this mode, the cryptographic operations are performed according to the rules of the FIPS 140-2 standard. The OpenSSL cryptographic library is used in the FIPS mode.

Select whether to use the Standard or the FIPS 140-2 certified version of the cryptographic library.

For the default settings, see the section called “Defining Ciphers”, the section called “Defining MACs”, and for the profile-specific settings, see the section called “Defining Ciphers”, and the section called “Defining MACs”.

Connection Broker

Select whether to hide the Tectia tray icon from the Windows taskbar notification area, and whether to show the Exit and Configuration options in the shortcut menu.

File Security (Available on Linux, only)

Select the Check file and directory access permissions check box to enable checking the access permissions for the user-specific configuration file ($HOME/.ssh2/ssh-broker-config.xml) and the private key files. By default, file and directory access permissions are not checked.

When the file and directory access permissions are checked, the controls are applied as follows:

- Expected permissions for the user configuration file: only the user has read and write rights. If the permissions are any wider, the Connection Broker will not start.

- Expected permissions for the private key files: only the user has read and write rights. If the permissions are any wider, keys that do not pass the check will be ignored.

Defining Default Connection Settings

The Default Connection page allows you to edit the default settings for a user name (the section called “Defining Connection Settings”), authentication (the section called “Defining Authentication”), ciphers (the section called “Defining Ciphers”), MACs (the section called “Defining MACs”), KEXs the section called “Defining KEXs”, server connections (the section called “Defining Server Connections”), and tunneling (the section called “Defining Default Tunneling Settings”).

Newly created connection profiles will inherit the default settings defined here. The values can be customized on the profile-specific tabbed pages and they override the default settings. See the section called “Defining Authentication”, the section called “Defining Ciphers”, the section called “Defining MACs”, and the section called “Defining Server Connections”.

Defining Connection Settings

On the Connection tab, you can define a default user name to be used when connecting to remote servers. This connection is useful when several users will be using profiles jointly, either with their own system user names or with a common user account.

Figure A.4. The user name and network address family settings for connections

Select the Use current Windows user name option, to automatically apply the Windows user name of the currently logged in user to connections to remote servers.

Select the Specify user name option and enter a generic user name. Note that the name is case sensitive.

The given user name will be used in connections unless another user name is specified in a connection profile or connection attempt. In case you select this option but leave the user name field empty, the Connection Broker will prompt the user for a user name.

In principle, you can enter value "%USERNAME%", but it has the same effect as selecting Use current Windows user name.

If you specify a host name or the profile contains a host name, the Connection Broker will try to resolve the address based on the Network address family setting. If you select inet, the Connection Broker will
resolve the host name only with an IPv4 address. If you select `inet6`, the Connection Broker will resolve the host name only with an IPv6 address. Selecting `Any` means that the Connection Broker will resolve the host name with any IP address (IPv4 or IPv6) available.

**Note**

You can specify a direct IP address (either IPv4 or IPv6) for the connection using either the connection profile or the command line. This setting does not restrict the user specified network family address. For example, the connection will be established to a specified IPv4 address even if the network address family was set to IPv6.

Settings made in this tab take effect the next time a user logs in.

**Defining Authentication**

On the **Authentication** tab, you can define the default user authentication methods.

![Authentication methods for Tectia Client](image)

**Figure A.5. Authentication methods for Tectia Client**

Select the **Use factory defaults** check box to use the factory default authentication methods, or clear the check box to define a custom list of authentication methods.
In Tectia Client 6.4, the factory default authentication methods are, in order:

- Public-key
- Password
- Keyboard-interactive
- GSSAPI

The authentication methods are supported on all platforms, except for GSSAPI, which is not available on IBM z/OS.

To add a new authentication method to the list, click Add and select the method from the drop-down menu.

To remove an authentication method, select the method from the list and click Delete.

Use the arrow buttons to organize the preferred order of the authentication methods. The first method that is allowed by the Secure Shell server is used. Note that in some cases, the server may require several authentication methods to be passed before allowing login.

Possible methods for user authentication are:

- **Public-key**: Users are requested to use public-key authentication. See also Section A.1.4.
- **Password**: Users are requested to enter a password for authentication.
- **Keyboard-interactive**: Keyboard-interactive is designed to allow the Secure Shell client to support several different types of authentication methods, including RSA SecurID, and PAM. For more information on keyboard-interactive, see Section 4.8.
- **GSSAPI**: GSSAPI (Generic Security Service Application Programming Interface) is a common security service interface that allows different security mechanisms to be used via one interface. For more information on GSSAPI, see Section 4.9.

In the GSSAPI Authentication field, by selecting the Allow Ticket Forwarding check box you can enable Tectia Client to allow forwarding the Kerberos ticket over several connections.

When using Public-Key Authentication, you can also define which key types are used and how the keys are selected.

**Key selection** defines the policy Connection Broker uses when proposing user public keys to the server. Select the mode from the drop-down list. The options are:

- **Try available public keys automatically** (the default). With this policy, the client will try the keys in the following order:
  1. Keys with public key available and private key without a passphrase (no user interaction)
  2. Keys with public key available but private key behind a passphrase (require a passphrase query, provided the key is accepted by the server)
3. The rest of the keys, meaning keys that require a passphrase for the public key as well as the private key.

- **Prompt user to select the public key** - with this policy, the Connection Broker prompts the user to select the key from a list of available keys. If authentication with the selected key fails, the client will prompt the user again to select another key.

**Key types** defines whether only plain public keys or only certificates are tried during public-key authentication. Select the key type from the drop-down list. The default is to try both plain public keys and certificates.

By selecting the **Issuer must match server certificate issuer** check box, you can make the Connection Broker filter the user certificates that will be included in the list presented to the user. The client-side user certificates can be filtered according to their issuer name that is compared to the certificate issuers requested or accepted by the server. By default, the filtering is not done. This option is useful when a user has several certificates with different access rights to the same server, for example for a testing role and for an administrator role. The Connection Broker chooses the relevant certificates that are applicable on the remote host, and the user can choose the correct certificate from the short-listed ones.

To generate new public-key pairs and to upload the public part of the key to a server, click the **Public-Key Authentication Wizard** button. For more information, see the section called “Using the Public-Key Authentication Wizard”.

**Enabled algorithms** lists the public-key signature algorithms that are used for authenticating and signing the user’s public key. The algorithms that will be used are those that are configured for both Tectia Server and the Connection Broker. You can use the up and down arrow buttons to modify the order of the algorithms. To move an algorithm to the **Disabled algorithms** list, select it and click the right arrow button.

The factory default public-key signature algorithms are, in order:

- ssh-dss
- ssh-rsa
- ssh-dss-sha256 (Tectia)
- ssh-rsa-sha256 (Tectia)
- x509v3-sign-dss
- x509v3-sign-rsa
- x509v3-sign-dss-sha256 (Tectia)
- x509v3-sign-rsa-sha256 (Tectia)
- ssh-ed25519

**Defining Ciphers**

On the **Ciphers** tab, you can define the encryption algorithms used.
Figure A.6. Defining a cipher list

Select the Use factory defaults check box to use the factory default algorithms, or define a cipher list using the arrow buttons. The ciphers are tried in the order they are specified.

The factory default ciphers are, in order:

- CryptiCore (Tectia)
- AES-128-CBC
- AES-128-CTR
- AES-192-CBC
- AES-192-CTR
- AES-256-CBC
- AES-256-CTR
- 3DES
The ciphers that can operate in the FIPS mode are 3DES and both the CBC-mode and CTR-mode AES-128, AES-192, and AES-256.

Tectia proprietary algorithms are marked with **(Tectia)** and are operable with Tectia products only. They correspond to the algorithms that end with **@ssh.com** in the Connection Broker configuration file.

**Defining MACs**

On the **MACs** tab, you can configure the message integrity algorithms used.

![Figure A.7. Defining a MAC list](image)

Select the **Use factory defaults** check box to use the factory default algorithms, or define a MAC list using the arrow buttons. The MACs are tried in the order they are specified.

The factory default MACs are, in order:

- CryptiCore (Tectia)
- HMAC-SHA1
• HMAC-SHA1-96
• HMAC-SHA2-256
• HMAC-SHA256-2 (Tectia)
• HMAC-SHA224 (Tectia)
• HMAC-SHA256 (Tectia/Old)
• HMAC-SHA384 (Tectia)
• HMAC-SHA2-512
• HMAC-SHA512 (Tectia)
• HMAC-SHA2-256-ETM (OpenSSH)
• HMAC-SHA2-512-ETM (OpenSSH)

All the HMAC-SHA (both HMAC-SHA1 and HMAC-SHA2) algorithm variants listed above can operate in FIPS mode.

Tectia proprietary algorithms are marked with (Tectia) and are operable with Tectia products only. They correspond to the algorithms that end with @ssh.com in the Connection Broker configuration file.

**Defining KEXs**

On the **KEXs** tab, you can configure the key exchange methods used.
Figure A.8. Defining a KEX list

Select the **Use factory defaults** check box to use the factory default methods, or define a KEX list using the arrow buttons. The KEX methods are tried in the order they are specified.

The factory default KEXs are, in order:

- DH-GEX-SHA256
- DH-Group16-SHA512
- DH-Group18-SHA512
- DH-Group14-SHA256
- DH-Group14-SHA256 (Tectia)
- Curve25519-sha256
- DH-GEX-SHA1
- DH-Group14-SHA1
All the supported KEXs, except Curve25519-sha256 and Curve25519-sha256 (libssh), can operate in FIPS mode on Windows and Linux. For more information on the FIPS-Certified Cryptographic Library, see Section 3.6.3.

Tectia proprietary algorithms are marked with (Tectia) and are operable with Tectia products only. They correspond to the algorithms that end with @ssh.com in the Connection Broker configuration file.

Defining Server Connections

On the Server tab, you can define advanced server connection settings.

![Figure A.9. Defining server connection settings](image)

Use factory defaults

Select the check box to use the default values for the server connection settings.

Idle timeout

Specify how long idle time (after all connection channels are closed) is allowed for a connection before automatically closing the connection. The default is 5 seconds. Setting a longer time allows the
connection to the server to remain open even after a session (for example, Tectia SSH Terminal GUI) is closed. During this time, a new session to the server can be initiated without re-authentication. Setting the time to 0 (zero) terminates the connection immediately when the last channel to the server is closed.

**TCP Connection Timeout**

Specify for how long a TCP connection will be attempted to a Secure Shell server. Define the timeout in seconds, and after that time the TCP connection will be released in case the remote server is down or unreachable. Setting the value as 0 (zero) means this Tectia setting is disabled and the system default TCP timeout will be used. By default, the system timeout is used.

**Keepalive interval**

Specify an interval (in seconds) for sending keepalive messages to a Secure Shell server. The default is 0, meaning that no keepalive messages are sent.

**Exclusive connection**

Select this check box if you want always a new connection opened, instead of reusing a currently open connection.

**Show server banner**

Select this check box if you want to have the server banner message file (if it exists) visible to users before login.

**Show authentication success message**

Clear this check box if you do not want to have the `AuthenticationSuccessMsg` messages output and logged. By default the messages are enabled.

**SFTP compatibility mode**

Select a suitable mode for transferring files with SFTP. This setting affects the behavior of the `get/mget/sget` and `put/mput/sput` commands and the recursion level used by the `sftpg3` client. The following options are available:

- **Tectia** (the default) - `sftpg3` transfers files recursively from the current directory and all its subdirectories.
- **OpenSSH** - copies only regular files and symbolic links from the specified directory, and no subdirectories are copied. Otherwise the semantics of the `get` command are unchanged.
- **FTP** - the `get/put` commands are executed as `sget/sput` meaning that they transfer a single file, and no subdirectories are copied.

The recursion depth can be overridden by using the `sftpg3` client's commands `get/put/mget/mput` with command-line option `--max-depth="LEVEL"`. For more information, see `sftpg3(1)`.
Enabled Hostkey Algorithms

The host key signature algorithms used for server authentication with host keys or certificates are listed here. The algorithms that will be used are those that are defined in both Tectia Server and Connection Broker configuration files. This way the use of only certain algorithms, such as SHA-2, can be enforced by the server.

The host key algorithms are tried in the order they are specified. Exception: If a host key of a server already exists in the host key store of the client, its algorithm is preferred. You can use the up and down arrow buttons to modify the order of the algorithms.

The factory default host key algorithms are, in order:

- rsa-sha2-512
- rsa-sha2-256
- ssh-dss-sha256 (Tectia)
- ssh-rsa-sha256 (Tectia)
- ecdsa-sha2-nistp521
- ecdsa-sha2-nistp384
- ecdsa-sha2-nistp256
- ssh-rsa
- ssh-dss
- x.509v3-sign-dss
- x.509v3-sign-rsa
- x.509v3-sign-dss-sha256 (Tectia)
- x.509v3-sign-rsa-sha256 (Tectia)
- ssh-ed25519

Disabled Hostkey Algorithms

The host key algorithms listed here are not used for server authentication. To disable a host key algorithm, select it in the Enabled Hostkey Algorithms list and click the right arrow button.

Defining Default Tunneling Settings

On the Tunneling tab, you can define the default settings for X11 connections and agent forwarding (tunneling). The defaults are applied to new connection profiles and to those connection profiles that do not have their own tunneling settings defined.
Appendix A Connection Broker Configuration Tools

Figure A.10. Defining default tunneling settings

Select the **Use factory defaults** check box to apply the factory defaults for X11 and agent forwarding. According to the factory defaults, X11 forwarding is disabled (off) and agent forwarding is enabled (on).

To allow X11 forwarding on the client side, select the **Tunnel X11 connections** check box.

To disable agent forwarding on the client side, unselect the **Allow Agent Forwarding** check box.

**Defining Proxy Rules**

On the **Proxy Rules** page, you can define proxy rules to be used for connections.
Figure A.11. Defining proxy rules

To add a new proxy rule:

1. Click Add. The Proxy Rule dialog box opens.

2. Select the Type of the rule. The type can be Direct (no proxy), Socks4, Socks5, or Http.

Figure A.12. Defining proxy settings
For other types than direct, enter the proxy **Server** address and **Port**.

Select also whether the proxy rules applies to **Any** connection or only to connections to the specified **Network**. In the **Network** field, you can enter one or more conditions delimited by commas (,). The conditions can specify IP addresses or DNS names.

The IP address/port conditions have an address pattern and an optional port range (ip_pattern[:port_range]).

The `ip_pattern` may have one of the following forms:

- a single IP address `x.x.x.x`
- an IP address range of the form `x.x.x.x-y.y.y.y`
- an IP sub-network mask of the form `x.x.x.x/y`

The DNS name conditions consist of a hostname which may be a regular expression containing the characters "*" and "?" and a port range (name_pattern[:port_range]).

Click **OK**.

To edit a proxy rule, select a rule from the list and click **Edit**.

To delete a proxy rule, select a rule from the list and click **Delete**.

The rules are read from top down. Use the arrow button to change the order of the rules.

To use these general proxy rules with a connection profile, you must select to do so in the profile settings. See the section called “Defining Proxy Settings”.

**Defining Logging Settings**

On the **Logging** page, you can enable logging and customize the information that will be logged in the event log. By default logging is disabled.
Figure A.13. Logging settings

To enable logging of Tectia Client internal events, select how the logs will be saved. In the Log Destination field:

- Select File to have the log data saved in to a file named in the field on the right. Enter the exact file name or browse to an existing file.

- Select Event Log to have the Tectia Client data stored in the Event Log of the host.

Each program-internal event has an associated Action and Type. They have reasonable default values, which are used if no explicit logging settings are made.

The action can be either log or discard.

The event type can be one of the following:

- Informational
- Warning
- Error
- Security success
• Security failure

For a description of the log events, see Appendix E.

To change whether the event is logged or not, select an event from the list and click Log/Discard. You can select multiple events by holding down the SHIFT or CTRL key while clicking.

To customize the event action and type, select an event from the list and click Edit. You can select multiple events by holding down the SHIFT or CTRL key while clicking. The Edit Audit dialog box opens. Select the Action (log or discard) and the Type (informational, warning, error, security-success or security-failure) for the event and click OK.

Defining Clients Settings

On the Clients settings page, you can define settings related to clients.

![Figure A.14. Client settings](image)

GUI client

Use the Terminal selection option to define how the Tectia SSH Terminal GUI behaves when you select text with double-clicks. The options are:
• **select words** (the default) - selects a word at time, and uses space and all punctuation characters as delimiters.

• **select paths** - selects strings of characters between spaces, meaning a selection is extended over characters \ / . - _ so that, for example, a path to a file can be selected by double-clicking anywhere in the path.

Use the **Terminal bell** option to define whether Tectia terminal repeats audible notifications from the destination server. This option is only applied to connections with Unix servers. The options are:

• **system default alert** (the default), sounds the default alerts defined in the system on the destination server

• **using pc speaker** beeps the user's PC speakers

• **disable** mutes all audible notifications.

Select the **Close window after disconnect** option to define that also the Tectia SSH Terminal GUI window is to be closed while disconnecting from a server session by pressing CTRL+D. By default the terminal remains open, and only the server connection is closed.

**Command line clients**

The **Quiet mode** setting defines whether the command line clients should suppress warnings, error messages and authentication success messages. The setting affects the command line tools `scpg3`, `sshg3` and `sftpg3`.

### A.1.3 Defining Connection Profiles

Under **Connection Profiles** you can configure separate connection settings for each Secure Shell server you connect to. You can also configure several profiles for the same server, for example, with different user accounts.

Click **Test Connection** to open a connection to the remote server. You need to connect to the server once in order to get the server's host key. Tectia Client will prompt you to verify the received key. Check that it is valid, preferably by calling the server's administrator, and save the validated key. After this, the locally saved information on the key will be used in the authentication process automatically.

• To add a connection profile, click **Add profile** in the **Connection Profiles** page. Enter a name for the profile and click **OK**. By default, the profile name is also used as the hostname of the server.

Newly created connection profiles will inherit the default values for authentication, ciphers, MACs, KEXs, and advanced server settings defined under the **General → Defaults** page (the section called “Defining Default Connection Settings”). The values can be customized on the profile-specific tabbed pages.

Define the profile settings in the tabbed view as described in the section called “Defining Connection Settings”, the section called “Defining Authentication”, the section called “Defining Ciphers”, the

- You can organize the connection profiles in folders for each server you are connecting to. To add a folder for connection profiles, click **Add folder** in the **Connection Profiles** page. Enter a name for the folder and click **OK**. Add connection profiles to the folder by selecting the folder and clicking **Add profile**. The profile is created into the folder.

- To move a profile to a different profile folder, select the profile from the list and click **Move**. Select the folder where you want to move the profile from the drop-down list and click **OK**.

- To rename a connection profile or a profile folder, right-click on a profile or a folder name under **Connection Profiles** and click **Rename**. Type a new name, press **Enter**, and click **OK** or **Apply**.

- To remove a connection profile or a profile folder, select a profile or a folder and click **Delete**. You will be asked for confirmation. Click **OK** to proceed with the deletion.

  Note that removing a profile folder removes also all profiles in it.

**Defining Connection Settings**

On the **Connection** tab, you can define the protocol settings used in the connection. Any changed connection settings will take effect the next time you log in.
Figure A.15. Configuring connection profiles

Host Name

Specify the host name or the IP address of the remote host computer to which you want to connect with the profile.

Port Number

Define the listen port on the Secure Shell server. The default SSH port number is 22. In case you know that the remote server uses another port, enter the number in the Port Number field.

Note

A Secure Shell server program must be listening to the specified port on the remote host computer or the connection attempt will not succeed. If you are unsure which port the remote host computer is listening to, contact the system administrator of the remote host.

User Name

Select Use current Windows user name if the connection should always be made using the currently logged in Windows user name. This is similar to defining %USERNAME% (note the percent signs) as the user name. %USERNAME% reads the actual user name from an environment variable.
Select **Specify user name** and enter the user name, if you want to define the user name this profile will use when connecting to the remote host computer.

Select **Prompt user for the user name** if the user should enter the user name manually every time when connecting.

Select **Use the Default Connection's user name** if you want to apply the generic user name defined in the General - Default Connection settings.

**Advanced**

In **Compression**, select the desired compression setting from the drop-down menu. Valid choices are **zlib** and **none**. Compression is disabled by default.

In **Tunnel using profile**, use the drop-down list to select a profile for creating a nested tunnel. The first tunnel will be created to the server defined in the current connection profile, and from there, the second tunnel will be created to a host defined in the profile selected with the **Tunnel using profile** setting. By default, tunneling is disabled.

**Usage**

This field shows information on where the defined profile is used.

**Defining Authentication**

On the **Authentication** tab, you can define the user authentication methods for the profile.
1. Select the **Use Defaults** check box to use the authentication methods defined on the Default Connection page (the section called “Defining Authentication”), or clear the check box to define a custom list of authentication methods.

To add a new authentication method to the list, click **Add** and select the method from the drop-down menu.

To remove an authentication method, select a method from the list and click **Delete**.

Use the arrow buttons to organize the preferred order of the authentication methods. The first method that is allowed by the Secure Shell server is used. Note that in some cases, the server may require several authentication methods to be passed before allowing login.

Possible methods for user authentication are:

- **Public-key**: Use public-key authentication. See also Section A.1.4.

- **Password**: Use a password for authentication.
• **Keyboard-interactive**: Keyboard-interactive is designed to allow the Secure Shell client to support several different types of authentication methods, including RSA SecurID, and PAM. For more information on keyboard-interactive, see Section 4.8.

• **GSSAPI**: GSSAPI (Generic Security Service Application Programming Interface) is a common security service interface that allows different security mechanisms to be used via one interface. For more information on GSSAPI, see Section 4.9.

2. If you want to use the profile in non-interactive connections, you can select to store a password with the profile in the **Password Authentication** field.

   Select **Password** to enter the actual password string.

   Select **Password file** to enter a path to a file containing the password.

   Select **Password program** to enter a path to a program or a script that outputs the password.

   **Caution**

   If the password is given using this option, it is extremely important that the `ssh-broker-config.xml` file, the password file, or the program are not accessible by anyone else than the intended user.

   **Note**

   Any password given with the command-line options will override this setting.

3. In the **GSSAPI Authentication** field, by selecting the **Allow Ticket Forwarding** check box you can enable Tectia Client to allow forwarding the Kerberos ticket over several connections.

4. When using **Public-Key Authentication**, you can also define which key types are used and how the keys are selected.

   **Key selection** defines the policy Connection Broker uses when proposing user public keys to the server. Select the mode from the drop-down list. The options are:

   • **Try available public keys automatically** (the default). With this policy, the client will try the keys in the following order:

     a. Keys with public key available and private key without a passphrase (no user interaction)

     b. Keys with public key available but private key behind a passphrase (require a passphrase query, provided the key is accepted by the server)

     c. The rest of the keys, meaning keys that require a passphrase for the public key as well as the private key.
- **Prompt user to select the public key** - with this policy, the Connection Broker prompts the user to select the key from a list of available keys. If authentication with the selected key fails, the client will prompt the user again to select another key.

**Key types** defines whether only plain public keys or only certificates are tried during public-key authentication. Select the key type from the drop-down list. The default is to try both plain public keys and certificates.

By selecting **Issuer must match server certificate issuer**, you can make the Connection Broker filter the user certificates that will be included in the list presented to the user. The client-side user certificates can be filtered according to their issuer name that is compared to the certificate issuers requested or accepted by the server. By default, the filtering is not done. This option is useful when a user has several certificates with different access rights to the same server, for example for a testing role and for an administrator role. The Connection Broker chooses the relevant certificates that are applicable on the remote host, and the user can choose the correct certificate from the short-listed ones.

To generate a public-key pair and to upload it to the remote server, click the **Public-Key Authentication Wizard** button. For instructions, see the section called “Using the Public-Key Authentication Wizard”.

**Enabled algorithms** lists the public-key signature algorithms that are used for authenticating and signing the user's public key. The algorithms that will be used are those that are configured for both Tectia Server and the Connection Broker. You can use the up and down arrow buttons to modify the order of the algorithms. To move an algorithm to the **Disabled algorithms** list, select it and click the right arrow button.

5. Click OK to save the connection profile.

**Using the Public-Key Authentication Wizard**

On Windows, you can use the Tectia **Public-Key Authentication Wizard** to generate and to upload public-key pairs. The wizard will generate two key files, your private key and your public key.

The new private and public key will be stored on your local computer in the `%APPDATA%\SSH\UserKeys` directory. The private key file has no file extension, and the public key has the same base file name as the private key, but with `.pub` as the file extension.

Select the **Keys and Certificates** page under **User authentication** and click **New Key** to start the Public-Key Authentication Wizard.
Define the key properties and the required passphrase to protect your key pair; you will be requested to enter the passphrase always when using the keys to authenticate yourself.

**File Name**

Type a unique name for the key file. Tectia Client suggest a name consisting of the user name and the host name.

**Comment**

In this field you can write a short comment that describes the key pair. You can for example describe the connection the keys are used for. This field is not obligatory, but helps to identify the key later.

**Passphrase**

Type a phrase that you have to enter when handling the key. This passphrase works in a similar way to a password and gives some protection for your private key.

**Note**

In FIPS mode, due to a FIPS regulation which forbids exporting unencrypted private keys out of the FIPS module, it is not possible to generate user keys without a passphrase.

Make the passphrase difficult to guess. Use at least 8 characters, both letters and numbers. Any punctuation characters can be used as well.
Memorize the passphrase carefully, and do not write it down.

For connections where no user interaction is available, you can consider leaving the password empty.

**Retype passphrase**

Type the passphrase again. This ensures that you have not made a typing error.

Click the **Advanced Options**, to define the type of the key to be generated and the key length to be different from the defaults. By default, Tectia Client generates a pair of 2048-bit RSA keys.

In the **Key Properties** fields, you can make the following selections:

**Key Type**

Select the type of the key to be generated. Available options are DSA, RSA, ECDSA and Ed25519.

ℹ️ **Note**

Ed25519 keys are not available in FIPS mode.

**Key Length**

Select the length (complexity) of the key to be generated. Available options are:

- DSA/RSA keys: 1024, 2048, 3072, 4096, 5120, 6144, 7168, 8192 bits

ℹ️ **Note**

In FIPS mode (conforming to FIPS 186-3) the available DSA key lengths are limited to 1024, 2048 and 3072 bits.

- ECDSA keys: 256, 384, 521 bits

- Ed25519 keys: 512 bits

Larger keys of the same key type are more secure, but also slower to generate. A 256-bit ECDSA key and a 3072-bit DSA or RSA key provide equivalent security.

As soon as a new key has been generated, the Wizard proceeds to uploading the key to a remote server. In case you want to upload an existing key to a remote server, select the key file in the Keys and Certificates view, and click **Upload**. The following dialog appears in both cases:
Appendix A Connection Broker Configuration Tools

Figure A.18. Uploading a key

In the **Upload Public Key** view of the wizard, define the remote host where to upload the key:

**Quick connect**

Select this option to define the remote **Host name** and your **user name** there. The default Secure Shell port is 22.

**Connection profile**

Select a **Connection profile** from the drop-down list that specifies the desired remote host and user name.

Click **Upload** to upload the key to the selected server. If you are already connected to the remote server host, the key upload starts immediately. If you are not connected, you will be prompted to authenticate on the server (by default with password).

The public key will be uploaded to the default user home directory (`%USERPROFILE%\ssh2` on Windows, `$HOME/.ssh2` on Unix).

**Defining Ciphers**

On the **Ciphers** tab, you can define the encryption algorithms used for the profile.
Select the Use Defaults check box to use the algorithms defined on the Default Connection page (the section called “Defining Ciphers”), or define a cipher list using the arrow buttons. The ciphers are tried in the order they are specified.

Tectia proprietary algorithms are marked with (Tectia) and are operable with Tectia products only. They correspond to the algorithms that end with @ssh.com in the Connection Broker configuration file.

**Defining MACs**

On the MACs tab, you can configure the message integrity algorithms used for the profile.
Figure A.20. Defining a MAC list for the profile

Select the **Use Defaults** check box to use the algorithms defined on the **Default Connection** page (the section called “Defining MACs”), or define a MAC list using the arrow buttons. The MACs are tried in the order they are specified.

Tectia proprietary algorithms are marked with *(Tectia)* and are operable with Tectia products only. They correspond to the algorithms that end with *@ssh.com* in the Connection Broker configuration file.

**Defining KEXs**

On the **KEXs** tab, you can configure the key exchange methods used for the profile.
Select the **Use Defaults** check box to use the methods defined on the Default Connection page (the section called “Defining KEXs”), or define a KEX list using the arrow buttons. The KEXs are tried in the order they are specified.

Tectia proprietary algorithms are marked with *(Tectia)* and are operable with Tectia products only. They correspond to the algorithms that end with @ssh.com in the Connection Broker configuration file.

**Defining Server Connections**

On the **Server** tab, you can define advanced server connection settings for the profile.
Use Defaults

Select the check box to use the values defined on the Default Connection page (the section called “Defining Server Connections”) for the server connection settings.

Idle timeout

Specify how long idle time (after all connection channels are closed) is allowed for a connection before automatically closing the connection. The default is 5 seconds. Setting a longer time allows the connection to the server to remain open even after a session (for example, Tectia SSH Terminal GUI) is closed. During this time, a new session to the server can be initiated without re-authentication. Setting the time to 0 (zero) terminates the connection immediately when the last channel to the server is closed.

TCP connection timeout

Specify for how long a TCP connection will be attempted to a Secure Shell server. Define the timeout in seconds. After the defined time the TCP connection will be released in case the remote server is
down or unreachable. Setting the value as 0 (zero) means that the default system TCP timeout will be used.

Keepalive interval

Specify an interval (in seconds) for sending keepalive messages to a Secure Shell server. The default is 0, meaning that no keepalive messages are sent.

Exclusive connection

Select this check box if you want that the profile always opens a new connection, instead of reusing a currently open connection.

Show server banner

Select the check box if you want to have the server banner message file (if it exists) visible to users before login.

Enabled Hostkey Algorithms

This list shows the host key signature algorithms used for server authentication with host keys or certificates. The algorithms that will be used are those that are defined in both Tectia Server and Connection Broker configuration files. This way the use of only certain algorithms, such as SHA-2, can be enforced by the server.

The host key algorithms are tried in the order they are specified, with one exception: If a host key of a server already exists in the host key store of the client, its algorithm is preferred. You can use the up and down arrow buttons to modify the order of the algorithms.

Disabled Hostkey Algorithms

The host key algorithms listed here are not used for server authentication. To disable a host key algorithm, select it in the Enabled Hostkey Algorithms list and click the right arrow button.

Defining Proxy Settings

On the Proxy tab, you can select proxy settings for the profile.
Appendix A Connection Broker Configuration Tools

Figure A.23. Defining proxy settings for the profile

No proxy

Select this option if you do not want to use a proxy.

Use proxy rules

Select this option to use the proxy rules defined in the General settings Proxy Rules page (the section called “Defining Proxy Rules”).

Specify a proxy for this profile only

Click Add to add a new proxy definition for this profile.

Figure A.24. Defining alternate proxy for the profile
Select the **Type** of the rule. The type can be **Direct**, **Socks4**, **Socks5**, or **Http**.

For other types than direct, enter the address of the proxy **Server** and **Port**.

**Defining Tunneling**

Tunneling, or port forwarding, is a way of forwarding otherwise unsecured TCP traffic through an encrypted Secure Shell connection (tunnel). You can secure for example POP3, SMTP, and HTTP connections that would otherwise be unsecured.

The tunneling settings for the connection profile are configured using the **Tunneling** tab. Any changed tunneling settings will take effect the next time you log in.

---

**Figure A.25. Defining tunneling through a profile**

**Note**

The client-server applications using the tunnel will carry out their own authentication procedures (if any) the same way they would without the encrypted tunnel.

**Forwarding Options**
It is possible to define separately for each connection profile whether X11 and/or agent forwarding are enabled, or whether the general default forwarding settings are applied to the profile.

**Use Defaults**

Select this option to make the profile follow the default settings for X11 and agent forwarding defined on the **Defaults - Tunneling** tab (the section called “Defining Default Tunneling Settings”).

**Tunnel X11 connections**

To allow X11 forwarding for this connection profile, select this check box.

Tectia Client can securely tunnel (forward) X11 graphic connections from the remote host computer to an X Windows server running on the local computer.

**Note**

A prerequisite for X11 tunneling is that you have an X emulator (such as eXceed or Reflection X) running in passive mode on the Windows computer.

To tunnel (forward) X11 traffic, do the following actions:

1. Install an X server (X emulation) program on Windows (eXceed, Reflection X, or the like).
2. Start Tectia Client.
3. Select the **Tunneling** tab of the Connection Profiles page and make sure that the **Tunnel X11 connections** check box is selected.
4. Save your settings for Tectia Client.
5. Restart Tectia Client and log into the remote host.
6. Start the X server (X emulation) program.
7. To test the tunneling, run xterm or xclock from Tectia Client.

For more information, see **Section 6.3**.

**Allow Agent Forwarding**

To allow agent forwarding on the client side for this connection profile, select this check box.

In agent forwarding, Secure Shell connections and public-key authentication data are forwarded from one server to another without the user having to authenticate separately for each server.

For more information, see **Section 6.4**.

**Local Tunnels**

There are two types of tunnels that can be defined for application tunneling, local (outgoing) tunnels and remote (incoming) tunnels.

Local tunnels protect TCP connections that your local computer forwards from a specified local port to a specified port on the remote host computer you are connected to. It is also possible to forward the
connection beyond the remote host computer, but the connection is encrypted only between Tectia Client and Tectia Server.

Remote tunnels protect TCP connections that a remote host forwards from a specified remote port to a specified port on your local computer.

To edit local tunnel definitions, click the **Local tunnels** tab.

To add a new local tunnel, click **Add**. The **Local Tunnel** dialog box opens.

![Local Tunnel dialog box](image)

**Figure A.26. Defining a local tunnel**

The following fields are used to define a local tunnel:

- **Type**: Select the type of the tunnel from the drop-down list. Valid choices are TCP and FTP. If you are tunneling an FTP connection, set the tunnel type as FTP. For other protocols, set the tunnel type as TCP.

  **Note**

  If the Secure Shell server and the FTP server are located on different computers, FTP tunneling works only if FTP is set to run in passive mode. If the Secure Shell server and the FTP server are located on the same computer, tunneling works regardless of whether FTP is running in passive or active mode. For more information on FTP tunneling, see Section 6.1.2.

- **Listen port**: This is the number of the local port which the tunnel listens to or captures.

  **Note**

  The protocol or application that you wish to create the tunnel for may have a fixed port number (for example 143 for IMAP) that it needs to use to connect successfully. Other protocols or applications may require an offset (for example 5900 for VNC) that you will have to take into account.

- **Allow local connections only**: Select this option if you want to allow only local connections to be made. This means that other computers will not be able to use the tunnel created by you. By default, only local connections are allowed. This is the right choice for most situations.

  Consider the security implications carefully if you decide to also allow outside connections.
• **Destination host**: This field defines the destination host for the tunneling. The default value is `localhost`.

**Note**

The destination host is resolved by the Secure Shell server, so here `localhost` refers to the Secure Shell server host you are connecting to.

• **Destination port**: The destination port defines the port that is used for the forwarded connection on the destination host.

To edit a tunnel definition, select a tunnel from the list and click **Edit**. The **Local Tunnel** dialog opens.

To delete a tunnel definition, select a tunnel from the list and click **Delete** to remove a tunnel. Note that the selected tunnel will be removed immediately, with no confirmation dialog.

For more information on local tunnels, see Section 6.1.

**Remote Tunnels**

Remote (incoming) tunnels protect TCP connections that the remote host forwards from a specified remote port to the specified port on your local computer.

Click the **Remote tunnels** tab to edit incoming tunnel definitions. Click **Add** to open the **Remote Tunnel** dialog box.

![Remote Tunnel dialog box]

**Figure A.27. Defining a remote tunnel**

The following fields are used to define a remote tunnel:

• **Type**: Select the type of the tunnel from the drop-down list. Valid choices are TCP and FTP. For more information on FTP tunneling, see Section 6.1.2.

• **Listen port**: Enter the port that the tunnel listens to or captures from the remote host computer.

**Note**

Privileged ports (below 1024) can be forwarded only when logging in with root privileges on the remote host computer.
• **Destination host**: Define the destination host for the port forwarding. The default value is localhost.

   **Note**

   Here localhost refers to your local computer. Also note that if the connection from the remote host computer is forwarded beyond your local computer, that connection is unsecured.

• **Destination port**: Define the port that is used for the forwarded connection on the destination host.

To edit a tunnel definition, select a tunnel from the list and click **Edit**. The **Remote Tunnel** dialog opens.

To delete a tunnel definition, select a tunnel from the list and click **Delete** to remove a tunnel. Note that the selected tunnel will be removed immediately, with no confirmation dialog.

For more information on remote tunnels, see **Section 6.2**.

**Defining Windows Settings**

The type of the Tectia window that is opened initially is configured using the **Windows** tab. The selected GUI version, **Tectia SSH Terminal GUI** or **Tectia Secure File Transfer GUI**, will be opened first when this profile is accessed.

![Figure A.28. Defining initial Tectia window type](image-url)

© 1995–2021 SSH Communications Security

Tectia® Client 6.4 User Manual

Corporation
**Note**

When a profile is added from the Tectia Connections Configuration GUI using the **Add Profile** option, the initial window type of the new profile is automatically set to be the same as in the current GUI view.

**Defining Color Settings**

The colors used in the Tectia SSH Terminal GUI can be selected using the **Colors** page.

The color settings can be defined either globally or per profile. When colors are defined in Tectia terminal Global Settings, the **Use Global Colors** option is not available, but the color settings will affect all connection profiles. See Section B.1.3.

![Figure A.29. Defining Tectia terminal colors](image)

**Use Global Colors**: Select this check box if you want to apply the global color settings to this profile. When this check box is selected, you cannot modify the color settings.
Text Colors

The text colors affect the terminal window background color and the color of text in both a connected window and a disconnected window.

- **Foreground**: Select the desired foreground color from the drop-down menu. Foreground color is used for text in a window that has a connection to a remote host computer. You can select from sixteen colors. Black is the default foreground color.

- **Background**: Select the desired background color from the drop-down menu. You can select from sixteen colors. White is the default background color.

- **Selection**: Select the desired background color for mouse-selected texts from the drop-down menu. You can select from sixteen colors. Aquamarine is the default selection color.

- **Disconnected**: Select the desired foreground color for terminal windows that have no connection to a remote host computer. You can select from sixteen colors. Gray is the default foreground color for a disconnected terminal window.

Cursor Color

Select the desired cursor color from the drop-down menu. You can select from sixteen colors. Navy is the default cursor color.

ANSI Colors

With ANSI control codes it is possible to change the color of text in a terminal window. With the ANSI Colors setting you can select to use this feature. Even if you disable ANSI colors, you can still select your favorite text and background colors to be used in the terminal window.

Select the Enable ANSI Colors check box to allow ANSI colors to be used in the terminal window. By default, ANSI colors are selected.

Reverse Colors

By reversing the display colors you can quickly change the display from positive (dark on light) to negative (light on dark) to improve visibility.

Select the Reverse Video check box to change the foreground color into background color and vice versa. This setting affects the whole terminal window when you click OK.

Defining Terminal Settings

The settings used for the Tectia Client terminal are configured using the Terminal tab. Keyboard mappings take effect when you start a new connection or reset the terminal.
Figure A.30. Defining Tectia terminal settings

User Defined Keymap File

Use this option to create additional keyboard shortcuts or to modify the existing ones. The additional key mappings are saved into a separate text file with the .sshmap file extension. The current keymap file is displayed in the text field.

If you have defined an alternative keymap settings file, you can load it by typing the path and file name in the text field, or by clicking Browse. Clicking Browse will open an Open dialog box that allows you to locate an alternative keymap file.

You can modify the current key mappings and add new ones by clicking Edit. Clicking Edit will open the Tectia Keymap Editor, where you can create a new key mapping by clicking Add. Clicking Add will open the Tectia Shortcut dialog box.

To define a keyboard shortcut, on the Function drop-down list, select the function you want to map a key to. Depending on the function, you may further define it using an additional text box or drop-down list that appears when you select a function. In the text box in the lower left of the dialog box, press the key or key combination you want to map to the function.
To use the new key mapping, restart Tectia Client and reconnect to the server using the same connection profile for which you made the mapping. Notice that the key mapping only applies to this specific connection profile.

**Predefined Keyboard Inputs**

Select the **Backspace sends Delete** check box if you want to map the Backspace key to the Delete operation.

Select the **Delete Sends Backspace** check box if you want to map the Delete key to the Backspace operation.

Select the **Enter sends CR + LF** check box if you want to map the Enter key to send the carriage return (CR) and line feed (LF) characters. Otherwise only the line feed character will be sent.

Select the **Lock Function Keys** check box if you want to lock the function keys.

Select the **Line Wrap** check box if you want the text lines to wrap at the terminal window edge. By default, line wrapping is on.

Select the **Use Alt as meta key (send Escape)** check box if you want the Alt key to function as the meta key in the same way as the Escape key. If this option is selected, you can for example press the Alt+X key combination to simulate the Escape followed by X.

**Keypad Mode**

Select how you want the numeric keypad on the right-hand side of the regular keyboard to function.

Select **Numeric Keypad** to use the keypad to enter numbers.

Select **Application Keypad** to use the keypad for application control (with the keypad keys functioning as cursor keys, Home, End, Page Up, Page Down, Insert and Delete).
Terminal answerback

Use the Terminal answerback drop-down list to select the same terminal answerback mode that is used by the Tectia Server related to the profile.

Euro character

Use the Euro character drop-down list to select the support mode for the euro character (€).

The supported options are Windows (where euro is mapped as 0x80) and ISO 8859-15 (euro mapped as 0xA4). Select the same character set that is used by the Tectia Server related to the profile.

Note however that enabling the euro character support will disable the 8-bit terminal control codes.

Defining File Transfer Settings

The File Transfer tab defines which files are transferred using ASCII mode and which newline conventions are applied.

Figure A.32. Defining Tectia file transfer settings
ASCII transfer with old servers

**Detect Windows server from the version string:** Secure Shell client and server exchange version strings when setting up the connection. Select this check box to automatically detect Windows servers and use the correct setting for them. For this feature to work correctly, the Windows server has to specify “windows” in its version string.

Select the Unix check box to use Unix compatible line breaks (LF).

Select the Windows check box to use Windows compatible line breaks (CRLF).

Select the Ask before ASCII transfer check box to make Tectia Client ask you to specify the server type before each ASCII file transfer.

Defining Favorite Folders

In the Favorites Folders tab, you can create a list of commonly used remote directories. These favorites can then be easily selected from a drop-down menu in the file transfer window.

![Favorite Folders Tab](image)

**Figure A.33. Defining favorite remote folders for file transfer**
Favorite Folders

This list contains the favorite folders you have defined for the current connection profile. You can add, remove, and sort the favorites by using Add, Delete, and the arrow buttons below the list.

If you are defining a remote favorite that is located on a Windows Secure Shell server, the folder on the Windows server must be specified as follows: \drive/folder/subfolder.

A valid favorite folder definition would be, for example:

/C/Documents and Settings/All Users/Desktop

Home Folder

In the Home Folder field you can enter the directory where any new SFTP connections associated with this profile will start. If you leave the field empty, new connections will use the remote home folder that has been specified for your user account on the remote host computer.

A.1.4 Defining User Authentication

Under User Authentication, you can configure settings related to public-key and certificate authentication. See the section called “Managing Keys and Certificates” and the section called “Managing Key Providers”.

To enable or disable public-key authentication, see the section called “Defining Default Connection Settings” and the section called “Defining Authentication”.

Managing Keys and Certificates

On the Keys and Certificates page, you can add key and certificate files used in user authentication and directories for them, generate a new key, upload a key to a server, or change the passphrase for a key.
Figure A.34. Defining keys and certificates

Default keys

The default location of user keys.

Default certificates

The default location of user certificates.

Additional Directories and Files

Additional key directories and files explicitly added to the Tectia Client configuration.

- Click the Add directory button to add a directory of keys or certificates.
- Click the Add file button to add a key or certificate file.

Tectia Client supports .pem format keys and certificates.

- Select a directory or a file and click the Delete button to remove it. The reference to the directory, the key or certificate file is removed from the configuration. The keys themselves are not removed from the disk.
Key and Certificate List

All public keys and certificates known to Tectia Client are listed in this field. That is, those keys and certificates stored in locations in Default keys, Default certificates and Additional Directories and Files fields. Also the keys and certificates from external key providers are shown here (see the section called “Managing Key Providers”.

The value shown in the Status field can be:

- **locked** - The file is passphrase protected and the passphrase is not known to the Connection Broker. Uploading the file to a remote host unlocks it.

- **open** - The passphrase is known to the Connection Broker.

- If the field is empty, the file is not passphrase protected.

You can modify the key details by selecting a key file in the list and clicking a button at the bottom.

Click **Change passphrase** to change the passphrase of a selected key. Note that the command may not be supported for all key types.

Click **Upload** to upload the key to a remote server. You can only upload plain public keys. See also the section called “Uploading Public Keys Automatically”.

Click **New key** to start the key generation wizard. The new key will be added to the Default keys directory and it will become visible in the Key and Certificate List field. For a description of the wizard, see the section called “Using the Public-Key Authentication Wizard”.

### Note

The user-specific Application Data directory, where the public key files are stored, is hidden by default. To view hidden directories, change the setting in Windows Explorer. For example, on Windows 7, select Organize → Folder and search options on the menu. On the View tab, under Hidden files and folders, select Show hidden files, folders and drives.

Managing Key Providers

On the **Key Providers** page you can define the settings of external key providers used in user authentication. Available key providers are Microsoft Crypto API and PKCS #11.
Figure A.35. Defining key providers

Microsoft Crypto API

Tectia Client can access keys via Microsoft Crypto API (MSCAPI). MSCAPI is a standard cryptographic interface used in Microsoft Windows systems.

Microsoft Crypto API (MSCAPI) providers can be enabled by selecting the Enable Microsoft Crypto API check box. If you enable the MSCAPI providers, you can use software keys and certificates created by Microsoft applications.

PKCS #11

By using the PKCS #11 provider, Tectia Client can use keys and certificates stored in PKCS #11 tokens (for example, smart cards or USB tokens).

Click Add to define a PKCS #11 provider.
Figure A.36. Defining a PKCS #11 provider, Aladdin eToken DLL path shown as an example

Use the **Dynamic library** to define a dynamic library containing the PKCS #11 driver.

Use the **Slots** to define slots. A slot is a logical reader that potentially contains a token. Slots are manufacturer- specific. They are defined with an integer. Examples: "0, 1", "0-3, !2", "2".

### A.1.5 Defining Server Authentication

Under **Server Authentication**, you can define how Tectia Client authenticates remote server hosts.

- To use public keys in server authentication, define the settings as described in the section called “Managing Host Keys”.

- To apply certificates, define the settings as described in the section called “Managing CA Certificates”.

- Settings required for LDAP usage are described in the section called “Managing LDAP Server Settings”.

- To define regular intervals for fetching certificate revocation lists (CRLs), see the section called “Managing CRL Prefetch Settings”.

**Managing Host Keys**

On the **Host Keys** page, you can add new public host keys, define the host key acceptance policy, and view and manage known host keys used in server authentication. Known host keys mean keys already stored to the user-specific `%APPDATA%\SSH\Hostkeys` directory.
Figure A.37. Defining server host keys settings

Note

The host key policy settings have changed in version 6.1.4. Tectia Connections Configuration GUI updates the user-specific configuration automatically to use the new policy based on the old **Strict host key checking. Accept unknown host keys**, and **Always show host key prompt** settings. The interpretation of the old policy to the new policy is shown in Table A.2.

The **Host Keys** view includes the following options:

**Check for Host Key**

You can check if a public host key of a remote server exists on your client, and view its fingerprint. To check the host key, enter the name of the server in the **Host** field and the listener port number in the **Port** field, and click **Check**.

Note that wildcard characters are not allowed, specify the exact host name and port.

When a public host key for the specified server is found on the client, a dialog-box shows where the host key is stored and what is the fingerprint of the public key. The displayed fingerprint formats can be selected from the **Fingerprint types** section. For example, with the default SHA-1 Babble and SHA-256 Base64 selected:
Delete Host Key

In case you want to delete a known public host key from the client side, enter the name of the relevant server in the **Host** field and the listener port number in the **Port** field, and click **Delete**.

A dialog box appears asking you to confirm or to cancel the deleting of the host key.

Add Host Key

Click the **Add Key** button to add a new host key to your known host keys directory. The Connection Broker opens a file manager view where you can browse to the key location and select the host key you want to copy.

Host Key Policy

Select the policy you want to apply to the checking of server host keys and to the handling of unknown server host keys.

**Note**

This setting strongly affects the security of the client side host.

The options are:

- **Ask** - the default - the user will be asked to verify and accept the server public host keys, if the keys are not found in the host key store or if the keys have changed. The user can decide whether the key is to be stored to `%APPDATA%\SSH\Hostkeys`, or used once without storing it, or cancelled. Connection is allowed only to a server whose host key is either found in the known host keys directory or accepted by the user currently.

  This policy requires an interactive connection to get a response from the user. If the **Ask** option is applied on a non-interactive connection, the connection will be closed.

- **Strict** - the connection to the server will be allowed only if the host key is found in the user's known host keys storage. Otherwise, the connection will be closed. This option expects that all acceptable server host keys have already been stored on the client. No new host key's will be stored, and connections to any servers that have changed host keys will be closed.
This option can be used on non-interactive connections, once the host keys have been received by other means. This policy provides maximum protection against man-in-the-middle attacks.

- **Trust on first use** - new host keys are stored without prompting the user to accept them. Connections to servers offering a changed host key will be closed. This policy should be used only when server host keys cannot be added to the key storage by any other means.

- **Advisory - not recommended** - new host keys are stored without prompting the user to accept them, and connections are allowed also to servers offering a changed host key. Changed keys are not stored on the client, and data about opening connections with them are logged, provided that logging is enabled on the Connection Broker.

If you choose this policy, make sure the Connection Broker has logging activated in the General - Logging view, see the section called “Defining Logging Settings”. Then you have the possibility to detect any connections with changed host keys in the logs.

⚠️ **Caution**

Consider carefully before you activate the Advisory policy, as it practically disables server authentication and makes the connection vulnerable to active attackers.

**Managing CA Certificates**

On the Certificates page, you can manage trusted CA certificates.

For more information on server certificate authentication, see Section 4.3.
To add a CA certificate, click the **Add** button and select the certificate you want to add.

You can add X.509 certificate(s) as such. To add certificates from a PKCS #7 package (*p7b*), you must first extract the CA certificates from the package by specifying the `-7` option with `ssh-keygen-g3` on the command line:

```
> ssh-keygen-g3 -7 certfile.p7b
```

You can then add the extracted CA certificates.

The following fields are displayed on the CA certificate list:

- **Issued to**: The certification authority to whom the certificate has been issued.
- **Issued by**: The entity who has issued the CA certificate.
- **Expiration date**: The date that the CA certificate will expire.
- **Filename**: The file containing the CA certificate.
CRL Checking

Select the **Disable** check box to prevent the use of a certificate revocation list (CRL). A CRL is used to check if any of the used server certificates have been revoked.

![Note](image)

Disabling CRL checking is a security risk and should be done for testing purposes only.

**OCSP responder URL**

The OCSP Responder Service provides client applications a point of control for retrieving real-time information on the validity status of certificates using the Online Certificate Status Protocol (OCSP).

For the OCSP validation to succeed, both the end-entity (=Secure Shell server) certificate and the OCSP responder certificate must be issued by the same CA. If the certificate has an Authority Info Access extension with an OCSP Responder URL, it is only used if there are no configured OCSP responders. It is not used if any OCSP responders have been configured.

If an OCSP responder is defined in the configuration file or in the certificate, it is tried first; only if it fails, traditional CRL checking is tried, and if that fails, the certificate validation returns a failure.

**Enable endpoint identity check**

 Specifies whether the client will verify the server's hostname or IP address against the **Subject Name** or **Subject Alternative Name** (DNS Address) specified in the server host certificate. By default, **Enable endpoint identity check** is enabled (option **yes**). The other options are **no**, and **ask**.

If **no** is selected, the fields in the server host certificate are not verified and the certificate is accepted based on the validity period and CRL check only.

![Caution](image)

Disabling the endpoint identity check on the client is a security risk. Then anyone with a certificate issued by the same trusted CA that issues the server host certificates can perform a man-in-the-middle attack on the server.

If **ask** is selected, the user will be prompted to verify the certificate information and to either accept or cancel the connection.

**Enforce digital signature in key usage**

One of the compliance requirements of the US Department of Defense Public-Key Infrastructure (DoD PKI) is to have the Digital Signature bit set in the Key Usage of the certificate. To fulfill the compliance requirement by enforcing digital signature in key usage, select this check box.

**Endpoint domain**

Specify the default domain used in the end-point identity check. This is the default domain part of the remote system name and it is used if only the base part of the system name is available.
If the default domain is not specified, the end-point identity check will still work with short host names. For example, when a user tries to connect to a host "rock" giving only the short host name and the certificate contains the full DNS address "rock.example.com", the connection will be opened and Tectia Client will issue a warning about accepting a connection to "rock".

**HTTP proxy URL**

Specify the HTTP proxy used when making LDAP or OCSP queries for certificate validity.

The format of the address is "http://username@proxy_server:port/network/netmask, network/netmask...". The network/netmask part is optional and defines the network(s) that are connected directly (without the proxy).

**SOCKS server URL**

Specify the SOCKS server used when making LDAP or OCSP queries for certificate validity.

The format of the address is "socks://username@socks_server:port/network/netmask, network/netmask...". The network/netmask part is optional and defines the network(s) that are connected directly (without the SOCKS server).

**Managing LDAP Server Settings**

On the **LDAP Servers** page, you can define LDAP servers used for fetching CRLs and/or subordinate CA certificates based on the issuer name of the certificate being validated.

CRLs are automatically retrieved from the CRL distribution point defined in the certificate to be verified if the point exists.
Figure A.40. Defining LDAP servers

To add an LDAP server, click the **Add** button. Define the hostname and port for the server.

![LDAP Server Configuration](image)

Figure A.41. Adding an LDAP server

To edit an LDAP server, select the server from the list and click **Edit**.

To delete an LDAP server, select the server from the list and click **Delete**.

**Managing CRL Prefetch Settings**

On the **CRL Prefetch** page, you can define certificate revocation lists (CRLs) to be fetched from the defined location at regular intervals. The CRL distribution point can be either a standard format LDAP or HTTP URL, or it can refer to a file. The file format must be either binary DER or base64, PEM is not supported.

CRLs are automatically retrieved from the CRL distribution point defined in the certificate to be verified if the point exists.
Figure A.42. Defining CRL prefetch settings

To add a CRL prefetch address, click Add. The CRL Prefetch dialog box opens.

Figure A.43. Adding a CRL prefetch setting

Enter the URL of the CRL distribution point and the Interval how often the CRL is downloaded and click OK. The default download interval is 3600 (seconds).

In case the CRL distribution point refers to a file, enter the file URL in this format:

file:///absolute/path/name

To edit an existing CRL prefetch setting, select the setting from the list and click Edit.

To delete an existing CRL prefetch setting, select the setting from the list and click Delete.

A.1.6 Defining Automatic Tunnels
On the **Automatic Tunnels** page, you can create listeners for local tunnels that are started automatically when the Connection Broker starts up. The actual tunnel is formed the first time a connection is made to the listener port. If the connection to the server is not open at that time, it will be opened automatically as well.

![Automatic Tunnels](image)

**Figure A.44. Defining automatic tunnels**

When the Connection Broker starts, the list of the automatic tunnels is read, and the connection initiating applications will be matched to the rules defined here.

Select **Automatic Tunnels** in the tree menu and click **Add** to open the **Automatic Tunnel** dialog box.

![Automatic Tunnel](image)

**Figure A.45. Adding a new automatic tunnel**
• **Type**: Select the type of the tunnel from the drop-down list. Valid choices are TCP and FTP.

• **Listen port**: This is the number of the local port that the tunnel listens to, or captures. Do not use a reserved port number.

  **Note**
  
  The protocol or application that you wish to create the tunnel for may have a fixed port number (for example 143 for IMAP) that it needs to use to connect successfully. Other protocols or applications may require an offset (for example 5900 for VNC) that you will have to take into account.

• **Allow local connections only**: If you want to allow only local connections to be made, leave this check box selected. This means that other computers will not be able to use the tunnel created by you. By default, only local connections are allowed. This is the right choice for most situations. You should carefully consider the security implications if you decide to also allow outside connections.

• **Destination host**: This field defines the destination host for the port forwarding. The default value is localhost.

  **Note**
  
  The value of localhost is resolved by the Secure Shell server, so here localhost refers to the Secure Shell host you are connecting to.

• **Destination port**: The destination port defines the port that is used for the forwarded connection on the destination host.

• **Tunnel using profile**: Select the profile to use for the tunnel.

To edit an automatic tunnel, select a tunnel from the list and click **Edit**.

To delete an automatic tunnel, select a tunnel from the list and click **Delete**.

For more information on tunneling, see Section 6.1.

### A.2 Configuration File for the Connection Broker

The elements of the XML-based Connection Broker configuration file `ssh-broker-config.xml` are described in `ssh-broker-config(5)`.  

© 1995–2021 SSH Communications Security

Corporation

Tectia® Client 6.4 User Manual
ssh-broker-config

ssh-broker-config — Tectia Connection Broker configuration file format

The Connection Broker configuration file ssh-broker-config.xml is used by Tectia Client on Unix and Windows. The Connection Broker configuration file must be a valid XML file that follows the ssh-broker-ng-config-1.dtd document type definition.

Connection Broker Files

The Connection Broker reads three configuration files (if all are available):

1. The ssh-broker-config-default.xml file is read first. It holds the factory default settings. It is not recommended to edit the file, but you can use it to view the default settings.

   This file must be available and correctly formatted for the Connection Broker to start.

2. Next, the Connection Broker reads the global configuration file. The settings in the global configuration file override the default settings.

   If the global configuration file is missing or malformed, the Connection Broker will start normally, and will read the user-specific configuration file, instead. A malformed global configuration file is ignored and the default settings or user-specific settings, if they exist, are used instead.

3. Last, the Connection Broker reads the user-specific configuration file, if it is available. The settings in the user-specific configuration file override the settings in the global configuration file, with the following exceptions:

   • The following settings from the user-specific configuration are combined with the settings of the global configuration file:

     • In general element, the key-stores, cert-validation and file-access-control settings

     • In profiles element, all settings

     • In static-tunnels element, all settings.

   • If a connection profile with the same name has been defined in both the global configuration file and user-specific configuration file, the latter one is used.

     • If the filter-engine settings have been defined in the global configuration file, and the file is valid (not malformed), those settings are used, and any filter-engine settings made in the user-specific configuration file are ignored.

   If the user-specific configuration file is missing, the Connection Broker will start using the previously read configuration files. However, if a user-specific configuration exists but is malformed, the Connection Broker will not start at all.

On Unix, the default configuration file locations are as follows:
Appendix A Connection Broker Configuration Tools

- the default configuration:
  `/opt/tectia/share/auxdata/ssh-broker-ng/ssh-broker-config-default.xml`

- the global configuration: `/etc/ssh2/ssh-broker-config.xml`

- the user-specific configuration: `${HOME}/.ssh2/ssh-broker-config.xml`

- the XML DTD:
  `/opt/tectia/share/auxdata/ssh-broker-ng/ssh-broker-ng-config-1.dtd`

Note

In Tectia Client 6.1 and earlier on Unix the default auxiliary data directory `auxdata` was located in `/etc/ssh2/ssh-tectia/`. If your `ssh-broker-config.xml` file was created for Tectia Client version 6.1 or earlier, please update its DOCTYPE declaration to contain the current path to the Connection Broker configuration file DTD directory: `/opt/tectia/share/auxdata/ssh-broker-ng/`.

On Windows, the default configuration file locations are as follows (where `<INSTALLDIR>` indicates the default Tectia installation directory on Windows, see Section 1.1.2):

- Default configuration: "<INSTALLDIR>\SSH Tectia AUX\ssh-broker-ng\ssh-broker-config-default.xml"

- Global configuration: "<INSTALLDIR>\SSH Tectia Broker\ssh-broker-config.xml"

- User-specific configuration: "%APPDATA%\SSH\ssh-broker-config.xml"

- XML DTD: "<INSTALLDIR>\SSH Tectia AUX\ssh-broker-ng\ssh-broker-ng-config-1.dtd"

The following sections describe the options available in the Connection Broker configuration file. For more information on the syntax of the configuration file, see Section A.5.

Environment Variables

Two kinds of environment variables can be used in the Connection Broker configuration file. In addition to the system-level environment variables, you can use special variables that are Tectia specific. The environment variables take precedence over the special variables. So if an environment variable and a special variable have the same name, the environment variable will be used.

All alphanumeric characters and the underscore `_` sign are allowed in environment variables. The variable name ends to the first character that is not allowed.

You can define for example file or directory paths with environment variables, and they will be expanded to their values as explained below.

`${VARIABLENAME}`

Replaced with the value of the environment variable if one has been defined. The variable is matched case-insensitively. If the variable is not defined, the string `${VARIABLENAME}` is the result.
$\text{VARIABLENAME}$

Replaced with the value of the environment variable if one has been defined. The variable is matched case-sensitively on Unix and case-insensitively on Windows. If the variable is not defined, it is replaced with an empty string.

$\{\text{VARIABLENAME}\}_text$

Replaced with the value defined for '$\text{VARIABLENAME}' with the 'text' appended to it.

$\{\text{VARIABLENAME}:default_value\}$

Replaced with the value defined for '$\text{VARIABLENAME}', or replaced with the 'default_value' if the variable is not set.

The Tectia specific special variables are:

%\text{U} or %\text{username}\%

Replaced with the currently logged in user name.

%\text{username}-without-domain\%

Replaced with the currently logged in user name in short format, i.e. without the domain part. Available on Windows.

%\text{G} or %\text{groupname}\%

Replaced with the group name of the currently logged in user.

%\text{D} or %\text{homedir}\%

Replaced with the home directory defined for the currently logged in user.

%\text{IU} or %\text{userid}\%

Replaced with the user identifier defined for the currently logged in user.

%\text{IG} or %\text{groupid}\%

Replaced with the group identifier defined for the currently logged in user.

The special variables can also be entered using the Unix format, for example, $\text{username}$.

**Document Type Declaration and the Root Element**

The Connection Broker configuration file is a valid XML file and starts with the Document Type Declaration.

The root element in the configuration file is secsh-broker. It can include general, default-settings, profiles, static-tunnels, gui, and logging elements.
An example of an empty configuration file is shown below:

```xml
<!DOCTYPE secsh-broker SYSTEM "ssh-broker-ng-config-1.dtd">
<secsh-broker version="1.0">
  <general />
  <default-settings />
  <profiles />
  <static-tunnels />
  <gui />
  <logging />
</secsh-broker>
```

**The general Element**

The `general` element contains settings such as the cryptographic library and the key stores to be used.

The `general` element can contain zero or one instance of the following elements: `crypto-lib`, `cert-validation`, `key-stores`, `user-config-directory`, `protocol-parameters`; and multiple `known-hosts` elements.

**crypto-lib**

This element selects the cryptographic library mode to be used. Either the standard version (`standard`) or the FIPS 140-2 certified version (`fips`) of the cryptographic library can be used. The library name is given as a value of the `mode` attribute. By default, standard cryptographic libraries are used. The OpenSSL cryptographic library is used in the FIPS mode.

FIPS mode will be used if it is so specified either in the global or the user configuration file (or both).

```xml
<crypto-lib mode="standard" />
```

In the FIPS mode, the cryptographic operations are performed according to the rules of the FIPS 140-2 standard. The FIPS library includes the `3des-cbc`, `aes128-cbc`, `aes128-ctr`, `aes192-cbc`, `aes192-ctr`, `aes256-cbc`, and `aes256-ctr` ciphers, and all the supported HMAC-SHA (both HMAC-SHA1 and HMAC-SHA2) variants of MAC. See `cipher` and `mac`.

For a list of platforms on which the FIPS library has been validated or tested, see *Tectia Client/Server Product Description*.

**cert-validation**

This element defines public-key infrastructure (PKI) settings used for validating remote server authentication certificates. The element can have the following attributes: `end-point-identity-check`, `default-domain`, `http-proxy-url`, `socks-server-url`, `cache-size`, `max-crl-size`, `external-search-timeout`, `max-ldap-response-length`, `ldap-idle-timeout` and `max-path-length`.

The `end-point-identity-check` attribute specifies whether the client will verify the server’s host name or IP address against the Subject Name or Subject Alternative Name (DNS Address) specified in
the server host certificate. The default value is yes. If set to no, the fields in the server host certificate are not verified and the certificate is accepted based on the validity period and CRL check only.

**Caution**

Setting end-point-identity-check="no" is a security risk. Then anyone with a certificate issued by the same trusted certification authority (CA) that issues the server host certificates can perform a man-in-the-middle attack on the server.

Alternatively, if set to ask, the user can decide to either cancel or continue establishing the connection in case that the server's host name does not match the one in the certificate.

The default-domain attribute can be used when the end-point identity check is enabled. It specifies the default domain part of the remote system name and it is used if only the base part of the system name is available. The default-domain is appended to the system name if it does not contain a dot (.).

If the default domain is not specified, the end-point identity check will still work with short host names. For example, when a user tries to connect to a host "rock" giving only the short host name and the certificate contains the full DNS address "rock.example.com", the connection will be opened and Tectia Client will issue a warning about accepting a connection to "rock".

The http-proxy-url attribute defines an HTTP proxy and the socks-server-url attribute defines a SOCKS server for making LDAP or OCSP queries for certificate validity.

The address of the server is given as the value of the attribute. The format of the address is socks:// username@socks_server:port/network/netmask, network/netmask ... (with a SOCKS server) or http://username@proxy_server:port/network/netmask, network/netmask ... (with an HTTP proxy).

For example, to make the SOCKS server use host socks.ssh.com and port 1080 for connections outside of networks 192.196.0.0 (16-bit domain) and 10.100.23.0 (8-bit domain), and to get these networks connected directly, set socks-server-url as follows:

"socks://mylogin@socks.ssh.com:1080/192.196.0.0/16,10.100.23.0/24"

The cache-size attribute defines the maximum size (in megabytes) of in-memory cache for the certificates and CRLs. The allowed value range is 1 to 512, and the default value is 35 MB.

The max-crl-size attribute defines the maximum accepted size (in megabytes) of CRLs. Processing large CRLs can consume a considerable amount of memory and processing power, so in some environments it is advisable to limit their size. The allowed value range is 1 to 512, and the default value is 11 MB.

The external-search-timeout attribute defines the time limit (in seconds) for external HTTP and LDAP searches for CRLs and certificates. The allowed value range is 1 to 3600 seconds, and the default value is 60 seconds.

The max-ldap-response-length attribute defines the maximum accepted size (in megabytes) of LDAP responses. The allowed value range is 1 to 512, and the default value is 11 MB.
The `ldap-idle-timeout` attribute defines an idle timeout for LDAP connections. The validation engine retains LDAP connections and reuses them in forthcoming searches. The connection is closed only after the LDAP idle timeout has been reached. The allowed value range is 1 to 3600 seconds, and the default idle timeout is 30 seconds.

The `max-path-length` attribute limits the length of the certification paths when validating certificates. It can be used to safeguard the paths or to optimize against the paths getting too long in a deeply hierarchical PKI or when the PKI is heavily cross-certified with other PKIs. Using the attributes requires knowing the upper limit of the paths used in certificate validation. For example:

```xml
<cert-validation max-path-length="6">
  <ldap-server address="ldap://myldap.com" port="389" />
  <dod-pki enable="yes" />
  <ca-certificate name="CA 1" file="ca-certificate1.crt" />
</cert-validation>
```

In the example, the path is limited to six certificates, including the end-entity and root CA certificates. If not specified, the default value is 10. Decrease the value to optimize the validation if the maximum length of the encountered paths in the certificate validation is known.

The `cert-validation` element can contain multiple `ldap-server`, `ocsp-responder`, `crl-prefetch` elements, one `dod-pki` element, and multiple `ca-certificate` and `key-store` elements. The elements have to be in the listed order.

**ldap-server**

This element specifies an LDAP server address and port used for fetching CRLs and/or subordinate CA certificates based on the issuer name of the certificate being validated. Several LDAP servers can be specified by using several `ldap-server` elements.

CRLs are automatically retrieved from the CRL distribution point defined in the certificate to be verified if the point exists.

The default value for `port` is 389.

**ocsp-responder**

This element specifies an OCSP (Online Certificate Status Protocol) responder service address in URL format with attribute `url`. Several OCSP responders can be specified by using several `ocsp-responder` elements.

If the certificate has a valid Authority Info Access extension with an OCSP Responder URL, it will be used instead of this setting. Note that for the OCSP validation to succeed, both the end-entity certificate and the OCSP Responder certificate must be issued by the same CA.

The `validity-period` (in seconds) can be optionally defined. During this time, new OCSP queries for the same certificate are not made but the old result is used. The default validity period is 0 (a new query is made every time).

**crl-prefetch**
This element instructs Tectia Client to periodically download a CRL from the specified URL. The url value can be an LDAP or HTTP URL, or it can refer to a local file. The file format must be either binary DER or base64. PEM is not supported.

To download CRLs from the local file system, define the file URL in this format:

```
file:///absolute/path/name
```

To download CRLs from an LDAP server, define the LDAP URL in this format:

```
ldap://ldap.server.com:389/CN=Root%20CA,OU=certification%20authorities,DC=company,DC=com?certificaterevocationlist
```

Use the interval attribute to specify how often the CRL is downloaded. The default is 3600 seconds.

**dod-pki**

One of the compliance requirements of the US Department of Defense Public-Key Infrastructure (DoD PKI) is to have the Digital Signature bit set in the Key Usage of the certificate. To enforce digital signature in key usage, set the value of the enable attribute to yes. The default is no.

**ca-certificate**

This element defines a certification authority (CA) used in server authentication. It can have four attributes: name, file, disable-crls, and use-expired-crls.

The name attribute must contain the name of the CA.

The element must either contain the path to the X.509 CA certificate file as a value of the file attribute, or include the certificate as a base64-encoded ASCII block.

CRL checking can be disabled by setting the disable-crls attribute to yes. The default is no.

Expired CRLs can be used by setting a numeric value (in seconds) for the use-expired-crls attribute. The default is 0 (do not use expired CRLs).

**key-store**

This element defines CA certificates stored in an external key store for server authentication. Currently it is used only on z/OS for CA certificates stored in System Authorization Facility (SAF).

An example of a certificate validation configuration is shown below:

```
<cert-validation end-point-identity-check="yes"
    default-domain="example.com"
    http-proxy-url="http://proxy.example.com:8080">
  <ldap-server address="ldap://ldap.example.com:389" />
  <ocsp-responder url="http://ocsp.example.com:8090"
```
**key-stores**

This element defines settings for user public-key and certificate authentication.

Under the `<general>` element, there can be one `<key-stores>` instance which in turn can have any number of `<key-store>`, `<user-keys>`, and `<identification>` elements, and the order of the elements is free.

Special variables and environment variables can be used when defining the values for the elements. The following variables can be used and they will be expanded as follows:

- `%U` = `%USERNAME%` = user name
- `%USERNAME-WITHOUT-DOMAIN%` = user name without the domain part
- `%IU` = `%USERID%` = user ID (not on Windows)
- `%IG` = `%GROUPID%` = user group ID (not on Windows)
- `%D` = `%HOMEDIR%` = the user's home directory
- `%G` = `%GROUPNAME%` = the name of the user's default group

Also environment variables are replaced with their current values. For example it is possible to use strings `%HOME` or `%HOMEDIR%` to expand to user's home directory (if environment variable HOME is set).

**Note**

Short alias names (for example, `%U`) are case-sensitive and long alias names (for example, `%USERNAME%`) are case-insensitive.

**key-store**

Each of the `<key-store>` elements configures one key store provider. The `<key-stores/key-store>` element can take the following attributes: `type` and `init`.

The `type` attribute is the key store type. The currently supported types are "mscap", "pkcs11", "software", and "zos-saf".

The `init` attribute is the initialization info specific to the key-store-provider. The initialization string can contain special strings explained above in `<key-stores>`.
For key store configuration examples, see the section called “Key Store Configuration Examples”.

**user-keys**

The `user-keys` element can be used to override the default directory for the user keys. The `user-keys` element can take the following attributes:

- **directory** attribute defines the directory where the user private keys are stored. Enter the full path.

- **passphrase-timeout** attribute defines the time (in seconds) after which the passphrase-protected private key will time out, and the user must enter the passphrase again. The default is 0, meaning that the passphrase does not time out. The value of this element should be longer than the `passphrase-idle-timeout` value.

By default, the Connection Broker keeps the passphrase-protected private keys open once the user has entered the passphrase successfully. This can be changed with the passphrase timeout options. When `passphrase-timeout` is set, the private key stays open (usable without further passphrase prompts) until the timeout expires. The `passphrase-timeout` attribute sets the hard timeout, that is set only once when the key is opened and will not be reset even if the key is used multiple times.

- **passphrase-idle-timeout** attribute defines the time (in seconds) after which the passphrase-protected private key will time out unless the user accesses or uses the key. The `passphrase-idle-timeout` is reset every time the key is accessed. The default is 0, meaning that the passphrase never times out.

Both of the timeout options can be set simultaneously, but notice that if the idle timeout is set longer than the hard timeout, the idle timeout has no effect.

**identification**

The `identification` element can be used to override the default location of the identification file that defines the user keys. The `identification` element can take the following attributes:

- **file** attribute specifies the location of the identification file. Enter the full path.

- **base-path** attribute defines the directory where the identification file expects the user private keys to be stored. This element can be used to override the default relative path interpretation of the identification file (paths relative to the identification file directory).

- **passphrase-timeout** attribute defines the time (in seconds) after which the user must enter the passphrase again. The default is 0, meaning that the passphrase is not re-requested.

- **passphrase-idle-timeout** attribute defines a time (in seconds) after which the passphrase times out if there are no user actions. The default is 0, meaning that the passphrase does not time out.

The timeout settings affect only those private keys that are listed in the identification file.
strict-host-key-checking

**Note**

This element is deprecated starting from Tectia Client version 6.1.4.

This element is supported in configuration for backwards compatibility and used only if the `policy` attribute of the `server-authentication-methods/auth-server-publickey` element under `default-settings` or `profiles/profile` is not defined. In this case, the host key policy is interpreted based on the values of this option and the `host-key-always-ask` and `accept-unknown-host-keys` options. See `auth-server-publickey` for details.

host-key-always-ask

**Note**

This element is deprecated starting from Tectia Client version 6.1.4.

This element is supported in configuration for backwards compatibility and used only if the `policy` attribute of the `server-authentication-methods/auth-server-publickey` element under `default-settings` or `profiles/profile` is not defined. In this case, the host key policy is interpreted based on the values of this option and the `strict-host-key-checking` and `accept-unknown-host-keys` options. See `auth-server-publickey` for details.

accept-unknown-host-keys

**Note**

This element is deprecated starting from Tectia Client version 6.1.4.

This element is supported in configuration for backwards compatibility and used only if the `policy` attribute of the `server-authentication-methods/auth-server-publickey` element under `default-settings` or `profiles/profile` is not defined. In this case, the host key policy is interpreted based on the values of this option and the `strict-host-key-checking` and `host-key-always-ask` options. See `auth-server-publickey` for details.

**Caution**

Consider carefully before enabling this option. Disabling the host-key checks makes you vulnerable to man-in-the-middle attacks.

user-config-directory

This element can be used to change the storage location of the user-specific configuration files away from the default which is `~/ssh2` on Unix, and `%APPDATA%\SSH` on Windows. It can be used for example, if you want to store all client-side configurations to a centralized location.

When this element is added to the global configuration file, the Connection Broker reads the following user-specific files in the defined location:
• User’s key file
• User’s own configuration files
• User’s known host keys
• User’s random_seed file
• Windows GUI profile files: 1.ssh2, 2.ssh2
• The startup batch file for the sftp3 client: ssh_sftp_batch_file

Note

Stop all existing SSH applications before modifying the user-config-directory setting in the Connection Broker configuration.

The user-config-directory setting affects all Tectia products running on the same host.

The user-config-directory option takes an attribute path, whose value can be either a directory path or one of the following variables:

• %U: The user name.
• %username%: The user name.
• %username-without-domain%: The user name without domain definition.
• %D: The user's home directory.
• %homedir%: The user's home directory.
• %USER_CONFIG_DIRECTORY%: The user-specific configuration directory.
• %IU: The user's ID, on Unix only
• %userid%: The user's ID, on Unix only
• %IG: The group ID, on Unix only
• %groupid%: The group ID, on Unix only

The default is %USER_CONFIG_DIRECTORY%. This variable refers to the user-specific configuration directory: $HOME/.ssh2 on Unix, and %APPDATA%\SSH on Windows. The %USER_CONFIG_DIRECTORY % variable cannot be used in other settings.

file-access-control

On Unix, this element can be used to enable checking of file access permissions defined for the global and user-specific configuration files, and for the private keys files. If the permissions are not as expected, the Connection Broker will refuse to start, or to use certain private keys.
By default this setting is disabled. On Windows, this element has no effect.

The file permissions are checked differently, if the `file-access-control` element is set in both the global and user configuration files, or just in one of them. See the following table for details:

**Table A.1. Different file-access-control effects**

<table>
<thead>
<tr>
<th>Setting in:</th>
<th>Permissions checked in:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Global config</td>
</tr>
<tr>
<td>yes</td>
<td>yes / -</td>
</tr>
<tr>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>no / -</td>
<td>yes</td>
</tr>
<tr>
<td>no / -</td>
<td>no / -</td>
</tr>
</tbody>
</table>

In the table: "no" means `file-access-control enable="no"`. The "-" sign means that the setting is not defined in the file at all.

When the file access permissions are checked, the controls are applied as follows:

- Expected permissions for the global configuration file: read rights for all, write rights only for the user and group. If the permissions are any wider, the Connection Broker will not start.
- Expected permissions for the user configuration file: only the user has read and write rights. If the permissions are any wider, the Connection Broker will not start.
- Expected permissions for the private key files: only the user has read and write rights. If the permissions are any wider, keys that do not pass the check will be ignored.

**protocol-parameters**

This element contains protocol-specific values that can be used to tune the performance. It should be used only in very specific environments. In normal situations the default values should be used.

The `threads` attribute can be used to define the number of threads the protocol library uses (fast path dispatcher threads). This attribute can be used to allow more concurrent cryptographic transforms in the protocol on systems with more than four CPUs. If the value is set to zero, the default value is used.

Example of the `threads` attribute:

```xml
<protocol-parameters threads="8" />
```

**known-hosts**

This element can be used to specify locations for storing the host keys of known server hosts, and to define the storage format of the host key files. If no `known-hosts` directories are specified, the known host keys are stored to the default directories. See the section called “Files” for the default locations. On z/OS (only), this element can contain `key-store` elements.

This element can be used:
• To specify non-default directories that contain the public-key data or public-key files of known server hosts.

• To specify a non-default location for OpenSSH-style known_hosts files that contain the public-key data of known server hosts.

• (On z/OS) To specify a SAF key store that contains the certificates of known server hosts.

The server host keys are searched in the known-hosts paths in the order they are specified in the configuration. The settings of the last defined known-hosts element are used when storing new host keys.

If you define any known-hosts file settings, the default OpenSSH files will be overridden. So if you wish to make the Connection Broker use both the default OpenSSH locations and other locations specified in the configuration, you need to specify all the locations separately.

You can define several known-hosts elements, and each of them can contain one or several attributes: path, directory, file and filename-format.

The path attribute requires a full path to the known-hosts file or directory as the value. For example:

```xml
<known-hosts path="/u/username/.ssh/known_hosts" />
<known-hosts path="/etc/ssh2/hostkeys" />
<known-hosts path="/u/username/.ssh2/hostkeys" />
<known-hosts path="/h/username/hostkeys" filename-format="plain" />
```

The directory attribute is used to define that known host keys are saved to a non-default directory. Enter the complete path to the directory as the value. If the defined directory does not exist, it will be created during the first connection attempt. If a file is found in its place, the connection will be made but the host key will not be stored, and the user gets a warning about it. The filename-format attribute can be used together with the directory setting to define in which format the host key files will be stored. Example of the directory attribute:

```xml
<known-hosts directory="<path_to_dir>/MyKEYS" filename-format="plain" />
```

The path or directory (whichever is present) defined in the last known-hosts element in the configuration file will be used when storing new known host keys. If both attributes are present in the last known-hosts element, the location specified in the directory attribute will be used.

The file attribute is used to point to an OpenSSH-style known_hosts file. Enter the complete path to the file as the value. If a directory is found in its place, it is considered an error, and the connection attempt will fail. In case the known-hosts element only contains the file attribute, and the defined OpenSSH known_hosts file exists, the received host keys are searched first in the defined file, and if not found there, the search continues in the default Tectia-specific locations.

Example of the file attribute:

```xml
<known-hosts file="<path_to_file>/.ssh2/openSSH_keys" />
```

An empty file or path attribute will disable the handling of the OpenSSH known_hosts file:
The `filename-format` attribute defines the format in which new host key files are stored. The `filename-format` attribute is only relevant for the last specified `known-hosts` element and for the default directory.

The `filename-format` attribute takes the values: hash (default), plain, and default (equals to hash).

With value hash, the host key files will be stored in format: `keys_<hash>`, for example "keys_182166d2efe5a134d3f8b948646e0b48f780bfff6c".

With value plain, the file name format will be `key_<port>_<hostname>.pub`, where `<port>` is the port the Secure Shell server is running on and `<hostname>` is the host name you use when connecting to the server; for example "key_22_my.example.com.pub".

Setting `<known-hosts filename-format="plain" />` changes the storage format of host key files for the next `known-hosts` elements or for the default storage location if no other `known-hosts` elements are present.

The `filename-format="default"` alternative can be used as the last option when the same `known-hosts` element is used to define several locations for the host keys some of which store the keys in plain format.

For more information on the host key storage formats, see Section 4.2.1.

**key-store**

This element defines an external key store for certificates of known server hosts. Currently it is used only on z/OS for server certificates stored in System Authorization Facility (SAF).

**extended**

This element is reserved for future use.

**Key Store Configuration Examples**

**Example with Software Provider**

The software provider handles key pairs stored on disk in standard Secure Shell v2 or legacy OpenSSH formats and X.509 certificates stored in native X.509, PKCS #7, and PKCS #12 formats.

To add a single key file (for example, `/u/exa/keys/enigma` and `/etc/my_key`), specify both the private key file and the public key file:
To add all keys from a specific directory (for example all keys from /u/exa/keys and /etc/keys):

```xml
<key-stores>
    <key-store type="software" init="directory(path(/u/exa/keys))" /> 
    <key-store type="software" init="directory(path(/etc/keys))" /> 
</key-stores>
```

Example with PKCS #11 Provider

The PKCS #11 provider handles keys and certificates stored in PKCS #11 tokens (for example, smart cards or USB tokens).

Specify the dynamic library path for the PKCS provider and all or a specific slot. For example, with all slots:

```xml
<key-stores>
    <key-store type="pkcs11" init="dll(/usr/lib/pkcs.so),slots(all)" /> 
</key-stores>
```

For example, with one slot named sesam:

```xml
<key-stores>
    <key-store type="pkcs11" init="dll(/usr/local/lib/pkcs.so),slots(sesam)" /> 
</key-stores>
```

The default-settings Element

The default-settings element defines the default connection-related settings. Profile-specific settings can override these settings. See the section called “The profiles Element”.

The default-settings element can contain zero or one instance of the following elements in the listed order: ciphers, macs, kexs, hostkey-algorithms, rekey, authentication-methods, hostbased-default-domain, compression, proxy, idle-timeout, tcp-connect-timeout, keepalive-interval, exclusive-connection, server-banners, forwards, extended, remote-environment, server-authorization-methods, authentication-success-message, sftp-g3-mode, terminal-selection, terminal-bell, close-window-on-disconnect, quiet-mode, checksum, and address-family.

The default-settings element can take one attribute:

The user attribute can be used to define a default user name to be used when connecting to remote servers. The value of the user attribute can be one of the following:

- A generic user name that will be used in connections unless another user name is specified in the connection profile settings or in the connection attempt. Note that the user name is treated case sensitively.
• "%USERNAME%" can be used to apply the user name of the currently logged in user.

• In case this option is used but left empty, the Connection Broker will prompt the user for a user name.

The default-settings element can contain the following elements:

ciphers

This element defines the ciphers that the client will propose to the server. The ciphers element can contain multiple cipher elements.

The ciphers are tried in the order they are specified.

cipher

This element selects a cipher name that the client requests for data encryption.

The supported ciphers are:

<table>
<thead>
<tr>
<th>Cipher 1</th>
<th>Cipher 2</th>
<th>Cipher 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>3des-cbc</td>
<td>aes128-cbc</td>
<td><a href="mailto:seed-cbc@ssh.com">seed-cbc@ssh.com</a></td>
</tr>
<tr>
<td>aes128-cbc</td>
<td>aes256-ctr</td>
<td>twofish-cbc</td>
</tr>
<tr>
<td><a href="mailto:aes128-gcm@openssh.com">aes128-gcm@openssh.com</a></td>
<td>arcfour</td>
<td>twofish128-cbc</td>
</tr>
<tr>
<td>aes192-cbc</td>
<td>AEAD_AES_128_GCM</td>
<td>twofish192-cbc</td>
</tr>
<tr>
<td>aes256-cbc</td>
<td>AEAD_AES_256_GCM</td>
<td>twofish256-cbc</td>
</tr>
<tr>
<td><a href="mailto:aes256-gcm@openssh.com">aes256-gcm@openssh.com</a></td>
<td>blowfish-cbc</td>
<td>none (no encryption)</td>
</tr>
<tr>
<td>aes128-ctr</td>
<td><a href="mailto:crypticore128@ssh.com">crypticore128@ssh.com</a></td>
<td></td>
</tr>
</tbody>
</table>

The default ciphers used by the Connection Broker are, in order: crypticore128@ssh.com (on Windows and Linux x86), aes128-cbc, aes128-ctr, aes192-cbc, aes192-ctr, aes256-cbc, aes256-ctr, and 3des-cbc.

The ciphers that can operate in the FIPS mode are 3des-cbc, aes128-cbc, aes128-ctr, aes192-cbc, aes192-ctr, aes256-cbc, and aes256-ctr.

<
ciphers
  
  <cipher name="aes128-cbc" />
  
  <cipher name="3des-cbc" />
  
</ciphers>

macs

This element defines the MACs that the client will propose to the server. The macs element can contain multiple mac elements.

The MACs are tried in the order they are specified.

mac

This element selects a MAC name that the client requests for data integrity verification.

The supported MAC algorithms are:
<table>
<thead>
<tr>
<th>MAC Type</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Crypticore-MAC</td>
<td><a href="mailto:crypticore-mac@ssh.com">crypticore-mac@ssh.com</a></td>
</tr>
<tr>

</tr>
<tr>
<td><a href="mailto:HMAC-SHA1-96-ETM@OPENSsh.COM">HMAC-SHA1-96-ETM@OPENSsh.COM</a></td>
<td><a href="mailto:hmac-sha1-96-ett@openssh.com">hmac-sha1-96-ett@openssh.com</a></td>
</tr>
<tr>
<td><a href="mailto:HMAC-SHA2-256-ETM@OPENSsh.COM">HMAC-SHA2-256-ETM@OPENSsh.COM</a></td>
<td><a href="mailto:hmac-sha2-256-ett@openssh.com">hmac-sha2-256-ett@openssh.com</a></td>
</tr>
<tr>
<td><a href="mailto:HMAC-SHA512-ETM@OPENSsh.COM">HMAC-SHA512-ETM@OPENSsh.COM</a></td>
<td><a href="mailto:hmac-sha512-ett@openssh.com">hmac-sha512-ett@openssh.com</a></td>
</tr>
</tbody>
</table>

The default MACs used by the Connection Broker are, in order:

- **crypticore-mac@ssh.com (on Windows and Linux x86)**
- hmac-sha1
- hmac-sha1-96
- hmac-sha2-256
- hmac-sha2-256-2@ssh.com
- hmac-sha224@ssh.com
- hmac-sha256@ssh.com
- hmac-sha256-2@ssh.com
- hmac-sha384@ssh.com
- hmac-sha384@ssh.com
- hmac-sha512@ssh.com
- hmac-sha512@ssh.com
- hmac-sha2-512
- hmac-sha2-512-ett@openssh.com
- hmac-sha2-256-ett@openssh.com
- hmac-sha2-256-ett@openssh.com

All the supported HMAC-SHA (both HMAC-SHA1 and HMAC-SHA2) algorithm variants can operate in the FIPS mode.

```xml
<macs>
  <mac name="hmac-sha1" />
</macs>
```

**kexs**

This element defines the key exchange methods (KEXs) that the client will propose to the server. The `kexs` element can contain multiple `kex` elements.

The KEXs are tried in the order they are specified.

**kex**

This element selects a KEX `name` that the client requests for the key exchange method.

The supported KEX methods are:

- `curve25519-sha256`
- `curve25519-sha256@libssh.org`
- `diffie-hellman-group1-sha1`
diffie-hellman-group14-sha1
diffie-hellman-group14-sha256
diffie-hellman-group16-sha512
diffie-hellman-group18-sha512
diffie-hellman-group14-sha224@ssh.com
diffie-hellman-group14-sha256@ssh.com
diffie-hellman-group15-sha256@ssh.com
diffie-hellman-group15-sha384@ssh.com
diffie-hellman-group16-sha384@ssh.com
diffie-hellman-group16-sha512@ssh.com
diffie-hellman-group18-sha512@ssh.com
diffie-hellman-group-exchange-sha1
diffie-hellman-group-exchange-sha256
diffie-hellman-group-exchange-sha224@ssh.com
diffie-hellman-group-exchange-sha384@ssh.com
diffie-hellman-group-exchange-sha512@ssh.com
ecdh-sha2-nistp256
ecdh-sha2-nistp384
ecdh-sha2-nistp521

The default KEX methods used by the Connection Broker are, in order:

diffie-hellman-group-exchange-sha256
diffie-hellman-group16-sha512
diffie-hellman-group18-sha512
diffie-hellman-group14-sha256
diffie-hellman-group14-sha256@ssh.com
curve25519-sha256@libssh.org
diffie-hellman-group-exchange-sha1
diffie-hellman-group14-sha1
curve25519-sha256@libssh.org is not supported in FIPS mode on any platform. All other supported KEXs can operate in FIPS mode on Linux, Windows, Solaris and HP-UX Itanium. However, the following supported KEXs cannot operate in the FIPS mode on HP-UX PA-RISC and IBM AIX due to issues in the OpenSSL cryptographic library version 0.9.8:

diffie-hellman-group15-sha256@ssh.com
diffie-hellman-group15-sha384@ssh.com
ecdh-sha2-nistp256
ecdh-sha2-nistp384
ecdh-sha2-nistp521

For more information on the FIPS-Certified Cryptographic Library, see Section 3.6.3.

<kexs>
  <kex name="curve25519-sha256@libssh.org" />
hostkey-algorithms

This element defines the host key signature algorithms used for server authentication. The algorithms that will be used are those that are defined in both Tectia Server and Connection Broker configuration files. This way the use of only certain algorithms, such as SHA-2, can be enforced by the server. The hostkey-algorithms element can contain multiple hostkey-algorithm elements.

The hostkey algorithms are tried in the order they are specified. Exception: If a host key of a server already exists in the host key store of the client, its algorithm is preferred.

hostkey-algorithm

This element selects a host key signature algorithm name to be used in server authentication with host keys or certificates.

The supported host key signature algorithms are:

```
ecdsa-sha2-nistp256
ecdsa-sha2-nistp384
ecdsa-sha2-nistp521
rsa-sha2-256
rsa-sha2-512
ssh-ed25519
ssh-dss
ssh-dss-sha224@ssh.com
ssh-dss-sha256@ssh.com
ssh-dss-sha384@ssh.com
ssh-dss-sha512@ssh.com
ssh-rsa
ssh-rsa-sha224@ssh.com
ssh-rsa-sha256@ssh.com
ssh-rsa-sha384@ssh.com
x509v3-sign-dss
x509v3-sign-dss-sha224@ssh.com
x509v3-sign-dss-sha256@ssh.com
x509v3-sign-dss-sha384@ssh.com
x509v3-sign-dss-sha512@ssh.com
x509v3-sign-rsa
x509v3-sign-rsa-sha224@ssh.com
x509v3-sign-rsa-sha256@ssh.com
x509v3-sign-rsa-sha384@ssh.com
x509v3-sign-rsa-sha512@ssh.com
```

The default host key signature algorithms used by the Connection Broker are, in order:

```
rsa-sha2-512
rsa-sha2-256
ssh-dss-sha256@ssh.com
ssh-rsa-sha256@ssh.com
ecdsa-sha2-nistp521
ecdsa-sha2-nistp384
ecdsa-sha2-nistp256
ssh-rsa
ssh-dss
x509v3-sign-dss
```
x509v3-sign-rsa
x509v3-sign-dss-sha256@ssh.com
x509v3-sign-rsa-sha256@ssh.com
ssh-ed25519

<hostkey-algorithms>
  <hostkey-algorithm name="ecdsa-sha2-nistp256" />
  <hostkey-algorithm name="ssh-ed25519" />
</hostkey-algorithms>

**rekey**

This element specifies the number of transferred bytes after which the key exchange is done again. The value "0" turns rekey requests off. This does not prevent the server from requesting rekeys, however. The default is 1000000000 (1 GB).

<rekey bytes="1000000000" />

**authentication-methods**

This element specifies the authentication methods that are requested by the client-side components. The *authentication-methods* element can contain one of each: auth-hostbased, auth-password, auth-publickey, auth-gssapi, and auth-keyboard-interactive. Alternatively, you can specify multiple *authentication-method* elements. The order of these elements is free.

The authentication methods are tried in the order the *auth-* or *authentication-method* elements are listed. This means that the least interactive methods should be placed first.

When several interactive authentication methods are defined as allowed, Tectia Client will alternate between the methods and offers each of them in turn to the server in case the previous method failed.

**authentication-method**

This element specifies an authentication method name. It is included for backwards compatibility. Use the *auth-* elements instead.

The allowed authentication method names are: gssapi-with-mic, publickey, keyboard-interactive, password, and hostbased.

Tectia Client supports host-based authentication only on Unix platforms.

<authentication-methods>
  <authentication-method name="hostbased" />
  <authentication-method name="gssapi-with-mic" />
  <authentication-method name="publickey" />
  <authentication-method name="keyboard-interactive" />
  <authentication-method name="password" />
</authentication-methods>

**auth-hostbased**

This element specifies that host-based authentication will be used.
The auth-hostbased element can include a local-hostname element.

local-hostname

This element specifies the local host name, as the value of the name attribute, that is advertised to the remote server during host-based authentication.

The remote server can use the client host name as a hint when locating the public key for the client host. This information is not significant to the authentication result, but makes it faster to find the relevant client host key, if the server has such a big storage of host identities, that trying them all would be infeasible.

auth-password

This element specifies that password authentication will be used.

auth-publickey

This element specifies that public-key authentication will be used.

The auth-publickey element can include a key-selection element.

The auth-publickey element can include a signature-algorithms attribute. The attribute defines the public-key signature algorithms used for client authentication, given as a comma-separated list. The algorithms that will be used are those that are defined in both Tectia Server and Connection Broker configuration files. This way the use of only certain algorithms, such as SHA-2, can be enforced. For a list of the supported algorithms, see hostkey-algorithm.

<authentication-methods>
  <auth-publickey signature-algorithms="ssh-dss,ssh-dss-sha512@ssh.com"/>
</authentication-methods>

key-selection

This element specifies the key selection policy the client uses when proposing user public keys to the server. The policy attribute can take the values automatic (default) and interactive-shy.

In the automatic mode, the client tries keys in the following order:

1. Keys with public key available and private key without a passphrase (no user interaction)
2. Keys with public key available but private key behind a passphrase (one passphrase query)
3. Keys that need a passphrase to get the public key but private key without passphrase (one user query for each key which is considered and proposed to server, but no user interaction for actual public-key login)
4. The rest of the keys, that is, keys that need a passphrase to get the public key and also to get the private key
In the `interactive-shy` mode, the client does not try any keys automatically, but it prompts the user to select the key from a list of available keys. If the authentication with the selected key fails, the client will prompt the user again, removing the already tried key(s) from the list. If there is only one key candidate available, the key will be tried automatically without asking the user.

The `key-selection` element can include the `public-key` and `issuer-name` elements.

**public-key**

This element can be used to specify that only plain public keys or only certificates are tried during public-key authentication. The `type` attribute can take the values `plain` and `certificate`. The default is to try both plain public keys and certificates.

**issuer-name**

This element can be used to filter the user certificates that will be included in the list presented to the user. The client-side user certificates can be filtered according to the issuer name that is compared to the certificate issuers requested or accepted by the server. The `match-server-certificate` attribute takes values `yes` and `no`. With value `yes`, Connection Broker tries matching the user certificate issuer name to the server certificate issuer name. Option `no` means that the issuer names are not used as a filter. By default, the filtering is not done.

The `issuer-name` is useful when a user has several certificates with different access rights to the same server, for example for a testing role and for an administrator role. The Connection Broker chooses the relevant certificates that are applicable on the remote host, and the user can choose the correct certificate from the short-listed ones.

**auth-keyboard-interactive**

This element specifies that keyboard-interactive methods will be used in authentication.

**auth-gssapi**

This element specifies that GSSAPI will be used in authentication.

The `auth-gssapi` element can take the following attributes:

The `dll-path` attribute specifies where the necessary GSSAPI libraries are located. If this attribute is not specified, the libraries are searched for in a number of common locations. The full path to the libraries should be given, for example, `"/usr/lib/libkrb5.so,/usr/lib/libgssapi_krb5.so"`.

On AIX, the `dll-path` should include the archive file, if applicable, for example, `"<path>/libgssapi_krb5.a(libgssapi_krb5.a.so)"`. The `archive(shared_object)` syntax is not necessary if the library is a shared object or has been extracted from the shared object.

On Windows, the `dll-path` attribute is ignored. Tectia Client locates the correct DLL automatically.
The `allow-ticket-forwarding` attribute defines whether Tectia Client allows forwarding the Kerberos ticket over several connections. The attribute can have a value of `yes` or `no`. The default is `no`.

An example of authentication-methods configuration is shown below:

```xml
<authentication-methods>
  <auth-hostbased>
    <local-hostname name="host.example.com" />
  </auth-hostbased>
  <auth-gssapi allow-ticket-forwarding="yes"/>
  <auth-publickey>
    <key-selection policy="interactive-shy">
      <public-key type="plain" />
    </key-selection>
  </auth-publickey>
  <auth-keyboard-interactive />
  <auth-password>
    <password file="/path/filename" />
  </auth-password>
</authentication-methods>
```

**hostbased-default-domain**

This element specifies the host's default domain name (as `name`). This element is used to make sure the fully qualified domain name (FQDN) of the client host is transmitted to the server when using host-based user authentication.

The default domain name is appended to the short host name before transmitting it to the server. This is needed because some platforms (Solaris for instance) use the short format of the host name, and with that the signature cannot be created.

The allowed formats of the default domain names are: `.example.com` and `example.com` (without the leading dot). For example:

```xml
<hostbased-default-domain name=".example.com" />
```

**compression**

This element specifies whether the client sends the data compressed (PUT operation). When activated, compression is applied on-the-fly to all data sent out through the connection and on all channels in it.

The name of the compression algorithm and the compression level can be given as attributes. The `name` attribute can be defined as `none` (compression not used) or `zlib`, currently the only supported algorithm. By default, compression is not used.

For zlib compression, the `level` attribute can be given an integer from 0 to 9. The default compression level is 6, when compression is activated but no level is given (or level is set to 0).

Example: to activate maximum level compression of sent data, make the following setting:

```xml
<compression name="zlib" level="9" />
```
Compression can also be activated per connection with command line tools. For information, see the sshg3(1), sftpg3(1) and scp4g3(1) man pages.

Note that this compression setting does not affect received data (GET operations), but their compression is defined on the Secure Shell server. Tectia Server always uses compression level 6.

**proxy**

This element defines rules for HTTP proxy or SOCKS servers the client will use for connections. It has a single attribute: ruleset.

The format of the attribute value is a sequence of rules delimited by semicolons (;). Each rule has a format that resembles the URL format. In a rule, the connection type is given first. The type can be direct, socks, socks4, socks5, or http-connect (socks is a synonym for socks4). This is followed by the server address and port. If the port is not given, the default ports are used: 1080 for SOCKS and 80 for HTTP.

After the address, zero or more conditions delimited by commas (,) are given. The conditions can specify IP addresses or DNS names.

```
direct://[cond[,cond]...];
socks://server/[cond[,cond]...];
socks4://server/[cond[,cond]...];
socks5://server/[cond[,cond]...];
http-connect://server/[cond[,cond]...]
```

The IP address/port conditions have an address pattern and an optional port range:

```
ip_pattern[:port_range]
```

The ip_pattern may have one of the following forms:

- a single IP address x.x.x.x
- an IP address range of the form x.x.x.x-y.y.y.y
- an IP sub-network mask of the form x.x.x.x/y

The DNS name conditions consist of a host name which may be a regular expression containing the characters "*" and "?" and a port range:

```
name_pattern[:port_range]
```

An example proxy element is shown below. It causes the server to access the loopback address and the ssh.com domain directly, access *.example with HTTP CONNECT, and all other destinations with SOCKS4.

```
<proxy ruleset="direct:///127.0.0.0/8,*.ssh.com;
          http-connect://http-proxy.ssh.com:8080/*.example;
          socks://fw.ssh.com:1080/" />
```

**idle-timeout**
This element specifies how long idle time (after all connection channels are closed) is allowed for a connection before automatically closing the connection. The time is given in seconds. The type is always connection.

The default setting is 5 seconds. Setting a longer time allows the connection to the server to remain open even after a session (for example, sshg3) is closed. During this time, a new session to the server can be initiated without re-authentication. Setting the time to 0 (zero) terminates the connection immediately when the last channel to the server is closed.

```
<idle-timeout time="5" />
```

tcp-connect-timeout

This element specifies a timeout for the TCP connection. When this setting is made, connection attempts to a Secure Shell server are stopped after the defined time if the remote host is down or unreachable. This timeout overrides the default system TCP timeout, and this timeout setting can be overridden by defining a tcp-connect-timeout setting per connection profile (in the profiles settings) or per connection (on command line).

The time is given in seconds. The factory default is 5 seconds. Value 0 (zero) disables this feature and the default system TCP timeout will be used.

```
<tcp-connect-timeout time="5" />
```

keepalive-interval

This element specifies an interval for sending keepalive messages to the Secure Shell server. The time value is given in seconds. The default setting is 0, meaning that the keepalive messages are disabled.

```
<keepalive-interval time="0" />
```

exclusive-connection

The exclusive-connection element can be used to specify that a new connection is opened for each new channel. This setting takes one attribute enable, with value yes or no. The default is no, meaning that open connections are reused for new channels requested by a client.

server-banners

This element defines whether the server banner message file (if it exists) is visible to the user before login. The word yes or no is given as the value of the visible attribute. The default is yes.

To eliminate server banners:

```
<server-banners visible="no" />
```

forwards

This element contains forward elements that define whether X11 or agent forwarding (tunneling) are allowed on the client side.

```
forward
```
This element defines X11 or agent forwarding settings.

The `type` attribute defines the forwarding type (either `x11` or `agent`). The `state` attribute sets the forwarding on, off, or denied. If the forwarding is set as denied, the user cannot enable it on the command-line.

An example forward configuration, which denies X11 forwarding and allows agent forwarding globally, is shown below:

```xml
<forwards>
  <forward type="x11" state="denied" />
  <forward type="agent" state="on" />
</forwards>
```

For more information on using X11 and agent forwarding, see Section 6.3 and Section 6.4.

extended

This element is reserved for future use.

remote-environment

This element contains `environment` elements which define the environment variables to be passed to the server from the client side. The environment variables are then set on the server when requesting a command, shell or subsystem.

Note that the server can restrict the setting of environment variables.

environment

This element defines the name and value of the environment variables, and whether the Connection Broker should process the value. Possible attributes are `name`, `value`, and `format`.

An example remote environment configuration:

```xml
<remote-environment>
  <environment name="FOO" value="bar" />
  <environment name="QUX" value="%Ubaz" format="yes" />
  <environment name="ZAPPA" value="%Ubaz" />
</remote-environment>
```

You can use `%U` in the `value` to indicate a user name. When `format="yes"` is also defined, the Connection Broker processes the `%U` into the actual user name before sending it to the server.

Let's assume the user name is `joedoe` in this example. The example configuration results in the following environment variables on the server side, provided that the server allows setting the environment variables:

```
FOO=bar
QUX=joedoebaz
ZAPPA=%Ubaz
```
You can override the remote environment settings made in the configuration file if you use the `sshg3` command with the following arguments on the command-line client: `--remote-environment` or `--remote-environment-format`.

For information on the command-line options, see `sshg3(1)`.

server-authentication-methods

This `server-authentication-methods` element can be used to force the Connection Broker to use only certain methods in server authentication. This element can contain `auth-server-publickey` and `auth-server-certificate` elements (one of each). The order of these elements is free.

If only `auth-server-certificate` is specified, server certificate is needed. If no server certificate is received, connection fails.

If only `auth-server-publickey` is specified, (plain) server public key is needed. If no server public key is received, connection fails.

If both `auth-server-certificate` and `auth-server-publickey` are specified, server certificate is used if present. Otherwise server public key is used.

auth-server-certificate

The `auth-server-certificate` element specifies that certificates are used for server authentication.

auth-server-publickey

The `auth-server-publickey` element specifies that public host keys are used for server authentication.

Note

The host key policy settings have changed in version 6.1.4 and are now defined in the `auth-server-publickey` element.

The element takes attribute `policy` that defines how unknown server host keys are handled. It can have the following values:

- strict: Connect to the server only if the host key is found from the host key store and matches. If the policy is set to `strict`, the Connection Broker never adds host keys to the user’s `.ssh2/hostkeys` directory upon connection, and refuses to connect to hosts whose key has changed. This provides maximum protection against man-in-the-middle attacks. However, it also means you must always obtain host keys via out-of-band means, which can be troublesome if you frequently connect to new hosts.

- ask (default): If the server host key is not found from the host key store, the user will be asked if he wants to accept the host key. If the host key has changed, the user is warned about it and asked how to proceed. If the client application is not able to ask the user (for example, `sftpg3` in batch mode, `-B`), the connection will be disconnected.
• **trust-on-first-use** or **tofu**: If the server host key is not found, it is stored to the user's `.ssh2/hostkeys` directory. If the host key has changed, the connection will be disconnected.

• **advisory**: Use of this setting effectively disables server authentication, which makes the connection vulnerable to active attackers.

If the server host key is not found in the host key store, it will be added to the user's `.ssh2/hostkeys` directory without user interaction. If the host key has changed, the connection will be continued without user interaction. The incident will be audited if logging is enabled.

When the policy is set to **advisory**, the keys from new hosts are automatically accepted and stored to the host key database without prompting acceptance from the user. However, changed host keys (from hosts whose keys are already in the database) are not stored, but they are accepted for that connection only.

This setting should be used only if logging is enabled for the Connection Broker.

**Caution**

Consider carefully before setting the policy to **advisory**. Disabling the host-key checks makes you vulnerable to man-in-the-middle attacks.

In policy modes other than **strict**, if logging is enabled for the Connection Broker, Tectia Client will log information about changed and new host public keys with their fingerprints in the syslog (on Unix) or Event Viewer (on Windows).

**Note**

When FTP-SFTP conversion is used, accepting the host key cannot be prompted from the user. Either the policy must be set to **tofu** or the host keys of the Secure Shell tunneling and SFTP servers must be obtained beforehand and stored based on the IP addresses of the servers.

If the **policy** attribute is not defined, the host key policy is interpreted based on the values of the old **strict-host-key-checking**, **host-key-always-ask**, and **accept-unknown-host-keys** options as shown in **Table A.2** below.

**Note**

In version 6.1.4 and later, the host key policy setting in the user-specific configuration file always takes precedence over the setting in the global configuration file.

**Table A.2. Interpretation of old host key policy (Tectia Client 5.0.0-6.1.3) to new host key policy (Tectia Client 6.1.4 and later)**

<table>

**authentication-method**

The `server-authentication-methods/authentication-method` element specifies an authentication method name. This element is included for backwards compatibility. Use the `auth-server-*` elements instead.

```xml
<server-authentication-methods>
  <authentication-method name="publickey" />
  <authentication-method name="certificate" />
</server-authentication-methods>
```

An example `server-authentication-methods` element is shown below:

```xml
<server-authentication-methods>
  <auth-server-publickey policy="ask" />
  <auth-server-certificate />
</server-authentication-methods>
```

**authentication-success-message**

This setting defines whether the `AuthenticationSuccessMsg` message is shown. The `authentication-success-message` element takes the attributes `enable` and `delay`.

Enable can be either yes or no. The default is yes, meaning that the messages are output and logged.

Delay takes a numerical value, which corresponds to how many seconds the authentication success message is shown. The default value is 2. When set to 0, the message is only logged, not shown.

Command-line client only.

**disconnect-message**

Message that displays as you disconnect (command-line client only). The value of the disconnect message is a string. The message may contain any number of the following substitution variables:

- **time**: Time of disconnect.
- **random**: 16 random hexadecimal digits.
- **random4**: 4 random hexadecimal digits.
• random8: 8 random hexadecimal digits.

• random16: Same as random.

• pid: Process id of sshg3.

• broker_pid: Broker process id.

• conn_id: Connection id.

• session_id: Session id.

• target_host: Target server name.

• target_port: Target server port.

If any of the random variables are used in a disconnect message, the random values are displayed to
the user before authentication successful message. If the values before the connection and after the
disconnect differ, somebody may be spoofing your connection.

Disconnect message is turned off by default.

keyboard-interactive

This setting contains the attribute prefix, which takes a string value. The prefix value will show
before of the keyboard-interactive prompt when set (command-line client only). The prefix attribute's
value can take the following substitution variables:

• time

• host

• port

• user

• connid

The default value for the prefix is $(host)>.

sftpg3-mode

This setting defines how the sftpg3 client behaves when transferring files. The sftpg3-mode element
takes attribute compatibility-mode with the following values:

• tectia (the default) - sftpg3 transfers files recursively, meaning that files from the current
directory and all its subdirectories are transferred.

• ftp - the get/put commands are executed as sget/sput meaning that they transfer a single file; and
commands mget/mput have recursion depth set to 1 meaning that they only transfer files from the
specified directory, not from subdirectories.
• **openssh** - commands `get/put/mget/mput` behave alike, and the recursion depth is set to 1, meaning that only files from the specified directory are transferred, not from subdirectories.

The recursion depth can be overridden by using the `sftpg3` client's commands `get/put/mget/mput` with command-line option `--max-depth="LEVEL"`. For more information, see `sftpg3(1)`.

**terminal-selection**

This element defines how the Tectia terminal behaves when the user selects text with double-clicks. The element takes one attribute: `selection-type`, whose value can be:

- `select-words` - double-clicking selects one word at a time, space and all punctuation characters are used as delimiters. This is the default.

- `select-paths` - selects strings of characters between spaces, meaning a selection is extended over characters `/\._-`, so that for example a path to a file can be selected by double-clicking anywhere in the path.

**terminal-bell**

This element defines whether Tectia terminal repeats audible notifications from the destination server. This option is only applied to connections with Unix servers. The element takes one attribute, `bell-style`, whose value can be:

- `none` - no audible notifications are used

- `pc-speaker` - the user's PC speakers beep when an audible notification is indicated by the destination server

- `system-default` - the Tectia terminal sounds the default alerts defined in the system on the destination server. This is the default.

**close-window-on-disconnect**

This element defines that also the Tectia terminal window is to be closed while disconnecting from a server session by pressing `CTRL+D`. The element takes one attribute, `enable`, whose value can be `yes` or `no`. The default is `no` meaning that `CTRL+D` closes only the server connection but the Tectia terminal window remains open.

**quiet-mode**

This setting defines whether the command line clients should suppress warnings, error messages and authentication success messages. The `quiet-mode` element takes attribute `enable` with value `yes` or `no`. The default is `no` meaning that the errors and messages are output and logged.

The `quiet-mode` element affects command line tools `scpg3`, `sshg3`, and `sftpg3`. Enabling the quiet mode here with setting `quiet-mode enable="yes"` is the same as running these clients with option `-q`. Note that the `-q` command line parameter will take priority over the `quiet-mode` element set in this configuration file.

**checksum**
The checksum element can be used to define a default setting for comparing checksums. This default overwrites the factory setting that checksums are not checked for files smaller than 32kB.

The checksum element takes attribute type, whose value can be:

- yes|YES - MD5 checksums are checked on files larger than 32kB. This is the default value.
- no|NO - checksums are not used.
- md5|MD5 - only MD5 checksums are checked on files larger than 32kB. When the --fips parameter is set with the command line clients scp3 and sftp3, this hash is not used.
- sha1|SHA1 - only SHA1 checksums are checked on files larger than 32kB. When the --fips parameter is set with the command line clients scp3 and sftp3, this hash is used.
- md5-force|MD5-FORCE - MD5 checksums are forced, except when the --fips parameter is set with the command line tools scp3 and sftp3.
- sha1-force|SHA1-FORCE - SHA1 checksums are forced on all files.
- checkpoint|CHECKPOINT - checkpointing is forced on large files that are transferred one by one.

Note

If the Connection Broker is started in FIPS mode and the md5 attribute is defined in the configuration file, but scp3 or sftp3 are not started with the --fips parameter, then md5 is used.

Note that checksums can also be defined with the command line clients scp3 and sftp3, or with environment variables. The order of priority of the three checksum settings (in case they are different) is as follows, the later one always overwrites the previous value:

- checksum setting in the configuration file
- SSH_SFTP_CHECKSUM_MODE environment variable
- Command line arguments

address-family

The address-family element defines the IP address family. Give the address family as the value of the type attribute. Tectia Client will operate using IPv4 (inet) addressing, IPv6 (inet6), or both (any). The default value for type is any.

The profiles Element

The profiles element defines the connection profiles for connecting to the specified servers. Element profiles can contain multiple profile elements. Each profile defines the connection rules to one server. The settings in the profile element override the default connection settings.
When a profile is used for the connection, the settings in the profile override the default settings. See the section called "The default-settings Element".

**profile**

The **profile** element defines a connection profile. It has the following attributes: id, name, host, port, protocol, host-type, connect-on-startup, user, and gateway-profile.

The profile id must be a unique identifier that does not change during the lifetime of the profile.

An additional name can be given to the profile. This is a free-form text string. The name can be used for connecting with the profile on the command line, so define a unique name for each profile.

The host attribute defines the address of the Secure Shell server host and it is a mandatory setting. The address can be either an IP address or a domain name. The value host="*" can be used to prompt the user to enter the host address when starting the session.

The port is a mandatory setting. It defines the port number of the Secure Shell server listener. The default port is 22.

The protocol is a mandatory setting. It defines the used communications protocol. Currently the only allowed value is secsh2.

If you want to make the connection specified by the profile automatically when the Connection Broker is started, set the value of the connect-on-startup attribute to yes. In this case, give also the user attribute (the user name the connection is made with). You also need to set up some form of non-interactive authentication for the connection.

The host-type attribute sets the server type for ASCII (text) file transfer. This specifies the line break convention that is used for ASCII files. The default value is default, meaning that the line break convention is determined by the local platform. If the client is running on Windows, Windows compatible line breaks (CR + LF, '\r\n') are used. If the client is running on any other platform, Unix compatible line breaks (LF, '\n') are used. Other possible values for host-type are windows (for Windows remote host) and unix (for Unix remote host). Define the value if you are using any other server than Tectia Server.

The user attribute specifies the user name for opening the connection. The value "%USERNAME%" can be used to apply the user name of the currently logged in user. The value user="*" can be used to prompt the user to enter the user name when logging in. When the user attribute is not defined, the user name defined in the default connection settings will be used.

The gateway-profile attribute can be used to create nested tunnels. The tunnels defined under the local-tunnel element of the profile, and the tunnels defined under filter-engine and static-tunnels that refer to the profile can be nested. The profile name through which the connection is made is given as the value of the attribute. The first tunnel is created using the gateway host profile and from there the second tunnel is created to the host defined in this profile.

**hostkey**
This element gives the path to the remote server host public key file as a value of the `file` attribute.

Alternatively, the public key can be included as a base64-encoded ASCII block.

ciphers

This element defines the ciphers used with this profile. See `ciphers` for details.

macs

This element defines the MACs used with this profile. See `macs` for details.

kexs

This element defines the KEXs used with this profile. See `kexs` for details.

hostkey-algorithms

This element defines the hostkey signature algorithms used with this profile. See `hostkey-algorithms` for details.

rekey

This element defines the rekeying settings used with this profile. See `rekey` for details.

authentication-methods

This element defines the authentication methods used with this profile. See `authentication-methods` for details.

user-identities

This element specifies the identities used in user public-key authentication. In contrast to the `key-stores` element that specifies all the keys that are available for the Connection Broker, this element can be used to control the keys that are attempted in authentication when this connection profile is used and to specify the order in which they are attempted.

The `user-identities` element can contain multiple `identity` elements. When multiple `identity` elements are used, they are tried out in the order they are listed.

identity

The `identity` element has the following attributes: `identity-file`, `file`, `hash`, `id`, and `data`.

The `identity-file` attribute specifies that the user identity is read in the identification file used with public-key authentication. Enter the full path to the file if it is located somewhere else than the default identification file directory which is `$HOME/.ssh2`. See also `ssh-broker-g3(1)`.
The `file` attribute specifies the path to the public-key file (primarily) or to a certificate. Enter the full path and file name as the value.

The `hash` attribute is used to enter the hash of the public key that will be used to identify the related private key. The key must be available for the Connection Broker. The public key hashes of the available keys can be listed with the `ssh-broker-ctl` tool. See also `ssh-broker-ctl(1)`.

The `id` attribute is reserved for future use.

The `data` attribute is reserved for future use.

An example `user-identities` element is shown below:

```xml
<user-identities>
  <identity identity-file="C:\\ mykey" />
  <identity file="$HOME/user/.ssh2/id_rsa_2048_a" />
  <identity file="C:\\private_keys\id_rsa_2048_a" />
  <identity hash="#a8edd3845005931aaa658b5573609e7d31e23af0d" />
</user-identities>
```

**compression**

This element defines the compression settings used with this profile. See `compression` for details.

**proxy**

This element defines the HTTP proxy and SOCKS server settings used with this profile. See `proxy` for details.

If `gateway-profile` has been defined for this profile, the proxy setting is ignored and the default proxy setting or the proxy setting of the gateway profile is used instead.

**idle-timeout**

This element defines the idle timeout settings used with this profile. See `idle-timeout` for details.

**tcp-connect-timeout**

This element defines the TCP connection timeout for this profile. The timeout is used to terminate connection attempts to Secure Shell servers that are down or unreachable. The default value is 5 seconds. See `tcp-connect-timeout` for details.

**keepalive-interval**

This element defines an interval for sending `keepalive` messages to the Secure Shell server. The setting applies to this profile. The default value is 0, meaning that no `keepalive` messages are sent. See `keepalive-interval` for details.

**exclusive-connection**
This element defines whether a new connection is opened for each new channel when a connection is made with this profile. This setting takes one attribute `enable`, with value `yes` or `no`. The default is `no`, meaning that open connections are reused for new channels requested by a client. See also `exclusive-connection`.

**server-banners**

This element defines the server banner setting used with this profile. See `server-banners` for details.

**forwards**

This element defines the forwards allowed with this profile. See `forwards` for details.

**tunnels**

The `tunnels` element defines the tunnels that are opened when a connection with this profile is made. The element can contain multiple `local-tunnel` and `remote-tunnel` elements.

**local-tunnel**

This element defines a local tunnel (port forwarding) that is opened automatically when a connection is made with the connection profile. It has five attributes: `type`, `listen-port`, `listen-address`, `dst-host`, `dst-port`, and `allow-relay`.

The `type` attribute defines the type of the tunnel. This can be `tcp` (default, no special processing), `ftp` (temporary forwarding is created for FTP data channels, effectively securing the whole FTP session), or `socks` (Tectia Client will act as a SOCKS server for other applications, creating forwards as requested by the SOCKS transaction).

The `listen-port` attribute defines the listener port number on the local client.

The `listen-address` attribute can be used to define which network interfaces on the client should be listened. Its value can be an IP address belonging to an interface on the local host. Value `0.0.0.0` listens to all interfaces. The default is `127.0.0.1` (localhost loopback address on the client). Setting any other value requires setting `allow-relay"yes"`.

For `address-family` option `inet6`, the default listen address is `::1`. To listen on all interfaces, specify `::`. For `address-family` option `any`, the listen address is both `127.0.0.1` and `::1` by default; to listen on all interfaces, specify `::`.

Whenever a connection is made to the specified listener, the connection is tunneled over Secure Shell to the remote server and another connection is made from the server to a specified destination host and port `(dst-host, dst-port)`. The connection from the server onwards will not be secure, it is a normal TCP connection.

The `dst-host` and `dst-port` attributes define the destination host address and port. The value of `dst-host` can be either an IP address or a domain name. The default is `127.0.0.1` (localhost = server host).
The **allow-relay** attribute defines whether connections to the listened port are allowed from outside the client host. The default is **no**. If you use **allow-relay="yes"**, it will check also the **listen-address** setting.

For more information on using local tunnels, see Section 6.1.

**remote-tunnel**

This element defines a remote tunnel (port forwarding) that is opened automatically when a connection is made with the connection profile. It has four attributes: **type**, **listen-port**, **listen-address**, **dst-host**, **dst-port**, and **allow-relay**.

The **type** attribute defines the type of the tunnel. This can be either **tcp** (default, no special processing) or **ftp** (temporary forwarding is created for FTP data channels, effectively securing the FTP session between the client and server).

The **listen-port** attribute defines the listener port number on the remote server.

The **listen-address** attribute can be used to define which network interfaces on the server should be listened. Its value can be an IP address belonging to an interface on the server host. Value **0.0.0.0** listens to all interfaces. The default is **127.0.0.1** (localhost loopback address on the server). Setting any other value requires that **allow-relay="yes"**.

For **address-family** option **inet6**, the default listen address is **::1**. To listen on all interfaces, specify **:**. For **address-family** option **any**, the listen address is both **127.0.0.1** and **::1** by default; to listen on all interfaces, specify **::**.

Whenever a connection is made to this listener, the connection is tunneled over Secure Shell to the local client and another connection is made from the client to a specified destination host and port (**dst-host**, **dst-port**). The connection from the client onwards will not be secure, it is a normal TCP connection.

The **dst-host** and **dst-port** attributes define the destination host address and port. The value of **dst-host** can be either an IP address or a domain name. The default is **127.0.0.1** (localhost = client host).

The **allow-relay** attribute defines whether connections to the listener port are allowed from outside the server host. The default is **no**.

For more information on using remote tunnels, see Section 6.2.

**extended**

This element is reserved for future use.

**remote-environment**

This element defines the remote environment settings used with this profile. Within the **remote-environment** element, define an **environment** element for each environment variable to be passed to the server. See **remote-environment** for details.
server-authentication-methods

This element defines the server authentication methods allowed with this profile. See server-authentication-methods for details.

password

This element can be used to specify a user password that the client will send as a response to password authentication.

The password can be given directly in the string attribute, or a path to a file containing the password can be given in the file attribute, or a path to a program or a script that outputs the password can be given in the command attribute.

When using the command option to refer to a shell script, make sure the script also defines the user's shell, and outputs the actual password. Otherwise the executed program fails, because it does not know what shell to use for the shell script. For example, if the password string is defined in a file named my_password.txt, and you want to use the bash shell, include these lines in the script:

```
#!/usr/bash
cat /full/pathname/to/my_password.txt
```

Caution

If the password is given using this option, it is extremely important that the ssh-broker-config.xml file, the password file, or the program are not accessible by anyone else than the intended user.

Note

Any password given with the command-line options will override this setting.

An example connection profile is shown below:

```
<profile name="rock"
  id="id1"
  host="rock.example.com"
  port="22"
  connect-on-startup="no"
  user="doct">
  <hostkey file="key_22_rock.pub">
  </hostkey>
  <authentication-methods>
    <auth-publickey />
    <auth-password />
  </authentication-methods>
</profile>
```
The **static-tunnels** Element

The **static-tunnels** setting is used to configure the behavior of the automatic tunnels. You can create listeners for local tunnels automatically when the Connection Broker starts up. The actual tunnel is formed the first time a connection is made to the listener port. If the connection to the server is not open at that time, it will be opened automatically as well.

The **static-tunnels** element can contain any number of **tunnel** elements.

**tunnel**

The **tunnel** element specifies a static tunnel. It has the following attributes: **type**, **listen-port**, **listen-address**, **dst-host**, **dst-port**, **allow-relay**, and **profile**.

The **type** attribute defines the type of the tunnel. This can be either **tcp** or **ftp**.

- **tcp** specifies a listener for generic TCP tunneling
- **ftp** specifies a listener for FTP tunneling (also the FTP data channels are tunneled)

The **listen-port** attribute defines the listener port number on the local client.

The **listen-address** attribute can be used to define which network interfaces on the client should be listened. Its value can be an IP address belonging to an interface on the local host. Value 0.0.0.0 listens to all interfaces. The default is 127.0.0.1 (localhost loopback address on the client). Setting any other value requires that **allow-relay**="yes".

For address-family option inet6, the default listen address is ::1. To listen on all interfaces, specify ::. For address-family option any, the listen address is both 127.0.0.1 and ::1 by default; to listen on all interfaces, specify ::.

The dst-host and dst-port attributes define the destination host address and port. The value of dst-host can be either an IP address or a domain name. The default is 127.0.0.1 (localhost = server host).

The allow-relay attribute defines whether connections to the listened port are allowed from outside the client host. The default is no.

The profile attribute specifies the connection profile ID that is used for the tunnel.

```xml
<static-tunnels>
  <tunnel type="tcp"
    listen-address="127.0.0.1"
    listen-port="9000"
    dst-host="st.example.com"
    dst-port="9000"
    allow-relay="no"
    profile="id1" />
</static-tunnels>
```

The gui Element

The gui element is used to adjust the Tectia terminal GUI settings. The gui element takes the following attributes: hide-tray-icon, show-exit-button, and show-admin. All of these must have yes or no as the value.

The hide-tray-icon attribute controls whether the Tectia icon is displayed in the notification area of the Windows taskbar (also known as the system tray). The default is no (the tray icon is displayed).

The show-exit-button attribute controls whether the Exit command is displayed in the shortcut menu of the Tectia icon. The default is yes.

The show-admin attribute defines whether the Configuration command is displayed in the Tectia icon shortcut menu. The default is yes. If the button is not displayed, the Tectia Connections Configuration GUI can be started by running ssh-tectia-configuration.exe, located by default in directory "<INSTALLDIR>\SSH Tectia Broker".

```xml
<gui hide-tray-icon="no"
    show-exit-button="yes"
    show-admin="yes" />
```

The logging Element

The logging element changes the logging settings that define the log event severities and logging facilities. The element contains one or more log-target and log-events elements.

log-target

This element specifies the log target for auditing. By default, the broker does not log anything. This element can be used to direct log data to a file or syslog.
The log-target element can have file and type as attributes.

The type attribute specifies the logging facility where the audit data is output to. The value can be file, syslog or discard.

The file attribute sets the file system path where the audit data is written to. If the type attribute has syslog or discard set, the file attribute is not allowed.

**log-events**

This element sets the severity and facility of different logging events. The events have reasonable default values, which are used if no explicit logging settings are made. This setting allows customizing the default values.

The element can also contain one or more log-target elements. When defined here, the log-target element will override the definition given in the logging/log-target.

For the events, facility and severity can be set as attributes. The events itself should be listed inside the log-events element.

The facility can be normal, daemon, user, auth, local0, local1, local2, local3, local4, local5, local6, local7, or discard. Setting the facility to discard causes the server to ignore the specified log events.

On Windows, only the normal and discard facilities are used.

The severity can be informational, notice, warning, error, critical, security-success, or security-failure.

Any events that are not specifically defined in the configuration file will use the default values. The defaults can be overridden for all remaining events by giving an empty log-events element after all other definitions and by setting a severity value for it.

In the names of log events, the characters '*' and '?' can be used as wildcards.

For a complete list of log events, see Appendix E.

An example logging configuration that logs all events, which are programmed to be logged by default, both to /tmp/foo and to syslog.

```xml
<logging>
  <log-target file="/tmp/foo" />
  <log-target type="syslog" />
</logging>
```

An example logging configuration in which events are logged to /tmp/foo, except those whose event name matches "Key_store_*", which will be discarded.

```xml
<logging>
  <log-target file="/tmp/foo" />
</logging>
```
A.3 Backup of Configuration Files

Before you start upgrades or creating test configurations, make sure you have a backup of the Connection Broker configuration files where you have made modifications.

The user-specific Connection Broker configuration file is by default located in $HOME/.ssh2/ssh-broker-config.xml on Unix and in %APPDATA%\SSH\ssh-broker-config.xml on Windows. Each time the Connection Broker configuration file is saved, a backup (ssh-broker-config.xml.bak) of the old configuration file is stored in the same directory. In case you need to return to using the backed up file, copy it back to the original location under the original name.

During Tectia upgrades on Windows, a backup copy is automatically made of the earlier Connection Broker configuration files and stored in the user-specific directory:

"%APPDATA%\SSH\backup-<version>--<date>"

where

<version> is the Tectia release

<date> is the date of the upgrade.

A.4 Connection Broker Configuration File Quick Reference

This Appendix contains a quick reference to the elements of the Connection Broker configuration file, ssh-broker-config.xml. The quick reference is divided into four tables:

• Table A.3: The general element

• Table A.4: The default-settings element

• Table A.5: The profiles element

• Table A.6: Other elements (static-tunnels, gui, and logging)

The tables list the available configuration file elements with their attributes, attribute values (with the default value, if available, marked in bold) and descriptions. The element names in the tables are links that take you to detailed descriptions of the elements in ssh-broker-config(5).

The element hierarchy is expressed with slashes ('/') between parent and child elements.

</table>
Element | Attributes and their values | Description
--- | --- | ---
profile / server-authentication-methods | Define the server authentication methods allowed with this profile using the same child elements as with default-settings / server-authentication-methods (see Table A.4)

profile / password | string = password | User password that the client will send as a response to password authentication

file = password_file | File containing the password
command = path | Path to a program or script that outputs the password

Table A.6. ssh-broker-config.xml Quick Reference - the static-tunnels, gui, and logging elements

Element | Attributes and their values | Description
--- | --- | ---
static-tunnels / tunnel | type = "tcp|ftp" | Type of the static tunnel

listen-address = IP_address (default: 127.0.0.1) | The network interfaces that should be listened on the client

listen-port = port_number | Listener port number on the local client

dst-host = IP_address|domain_name (default: 127.0.0.1) | Destination host address

dst-port = port_number | Destination port

allow-relay = "yes|no" | Allow connections to the listened port from outside the client host

profile = ID | Connection profile ID that is used for the tunnel

gui | hide-tray-icon = "yes|no" | Hide the Tectia icon in the Windows taskbar notification area

show-exit-button = "yes|no" | Show the Exit command in the Tectia icon's shortcut menu

show-admin = "yes|no" | Show the Configuration command in the Tectia icon's shortcut menu

logging / log-target | file = path | File where the audit data is written to

type = "file|syslog|discard" | Logging facility to which audit data is output

logging / log-events | facility = "normal|daemon
|user|auth|local0|local1|local2
|local3|local4|local5|local6
|local7|discard" | Facility of logging event
### A.5 Broker Configuration File Syntax

The DTD of the Connection Broker configuration file is shown below:

### Appendix A: Connection Broker Configuration Tools

---

The configuration tools for the Connection Broker are described using XML syntax. Below, we provide an overview of the various elements and attributes that can be configured:

- **id**: An identifier for the configuration element.
- **data**: Data associated with the configuration element.
- **password**: Specifies authentication information.
  - **string**: The password string.
  - **file**: Path to a file containing the password.
  - **command**: Command to generate the password.
- **proxy**: Defines proxy rules.
  - **ruleset**: The set of rules.
- **idle-timeout**: Configures idle timeouts.
  - **type**: Type of idle timeout.
  - **time**: Duration of the timeout.
- **tcp-connect-timeout**: Configuration for TCP connect timeouts.
  - **time**: Duration of the timeout.
- **keepalive-interval**: Specifies keepalive intervals.
  - **time**: Duration of the interval.
- **forwards**: Enables or disables for forwards.
  - **type**: Type of forward (x11|agent).
  - **state**: State of the forward (on|off|denied).
- **compression**: Enables or disables compression.
  - **name**: Name of the compression algorithm.
  - **level**: Compression level.
- **authentication-success-message**: EnablesQuiet mode.
  - **enable**: Enables or disables authentication success messages.
- **quiet-mode**: Enables or disables quiet mode.
  - **enable**: Enables or disables quiet mode.

A.6 Tectia Shortcut Menu (Windows and Linux)

When Tectia Client (or Connection Broker) is running on Windows or Linux, and if so selected in the **General** settings in the Tectia Connections Configuration GUI, the Tectia icon is displayed in the notification area of the Windows taskbar, typically next to the time display at the bottom of the desktop.

Right-click the Tectia icon to open the shortcut menu.

The contents of the shortcut menu can be modified in the Tectia Connections Configuration GUI in the **General** view (see Section A.1.2).
Figure A.46. The shortcut menu of the Status window

The menu has the following options:

- **Configuration** opens the Tectia Connections Configuration GUI.

- **Status** opens the **Tectia Connections Status GUI** where you can view information on the Connection Broker. For details, see Section A.6.1.

- **About** shows the installed Tectia Client version.

- **Stop Broker** stops the Connection Broker and closes all open connections.

- **Quit Status Monitor** closes the Tectia Connections Status GUI.

### A.6.1 Tectia Connections Status GUI

You can view information on the Tectia Connection Broker status in the **Tectia Connections Status GUI**.

To open the Tectia Connections Status GUI, click the Tectia icon  in the notification area of the Windows taskbar or right-click the icon and select the **Status** option from the shortcut menu. The Tectia Connections Status GUI gives you access to the following views: the **Connections**, **Keys**, and **Logs** views. Click a view icon on the left of the dialog box to see the relevant view.

#### Connections View

The **Connections** view of the Tectia Connections Status GUI displays the currently active secured connections (terminal, tunnel, or SFTP) to and from your computer.
The following information is displayed for each connection:

- **Connection**: The destination of the connection in the `user@host#port` format.
- **ID**: The identifier of the connecting program (a number issued by the Connection Broker).
- **Upload**: Amount of data uploaded (in bytes).
- **Download**: Amount of data downloaded (in bytes).
- **Upload speed**: Upload speed in kilobytes per second.
- **Download speed**: Download speed in kilobytes per second.

To view details about a connection, right-click the connection and select **Show Connection Status**. The view shows information related to authentication, transport and key exchange methods, amount of transferred data and open channels.

To view details about a channel, right-click the channel and select **Show Channel Status**. The view shows information related to the channel type, connection ID and host, duration and amount of transferred data.

To upload a key to the host, right-click the connection or channel and select **Upload Key**. The **Public-Key Authentication Wizard** opens where you can select the key to be uploaded and then upload the key. After a successful upload, the status of the upload and the destination where the key was uploaded are shown. For more information, see the section called “Using the Public-Key Authentication Wizard”.

To close an open connection, right-click the connection and select **Disconnect**.

To close an open channel, right-click the channel and select **Terminate channel**.

### Keys View
The **Keys** view of the Tectia Connections Status GUI displays the public keys and certificates that are available for public-key authentication.

### Figure A.48. The Keys view of the Status window

The following information is displayed for each key or certificate:

- **ID**: The identifier of the key (a number issued by the Connection Broker).
- **Provider**: Name of the key provider.
- **File name**: Name of the key file.
- **Status**: Status of the key can be:
  - **locked**: The file is passphrase or PIN protected and it is not known to the Connection Broker. Using the **Prompt PIN** shortcut command to give the passphrase unlocks the key.
  - **open**: The passphrase or PIN is known to the Connection Broker.
- **Type**: Type of the key (RSA, DSA, ECDSA or Ed25519) or the certificate (X.509 Certificate).
- **Comment**: Details about the key, such as length of the key, creator, and creation date and time.

To view details about a public key, right-click the public key and select **Show key information**. The view shows information related to the key type and length, its name, location and fingerprint, and whether its authentication code, for example a passphrase, is provided or not.

To clear the passphrase or PIN from cache, right-click the key and select **Clear cached PIN**. The key status changes to locked.

To save the passphrase or PIN into cache, right-click a locked public key and select **Prompt PIN**. A dialog opens prompting the passphrase or PIN. The key status changes to open.
To save the public key, right-click the key and select Save Public Key. The Save Public Key dialog opens for saving the key.

To upload a public key to a host, right-click the key and select Upload Public Key. The Public-Key Authentication Wizard opens where you can define a connection to a host and then upload the public key there. After a successful upload, the status of the upload and the destination where the key was uploaded are shown. For more information, see the section called “Using the Public-Key Authentication Wizard”

Logs View

The Logs view of the Tectia Connections Status GUI displays logged information of the currently secured connections.

![Figure A.49. The Logs view of the Status window](image)

To set the debugging level, enter a value in the field and click Set or press Enter.

You can select text from the log with the mouse and copy it to the clipboard with Ctrl+C. Pressing Ctrl+A selects all contents of the log. These commands are also available from a shortcut menu (right-click the log).

To pause the log creation, click Pause log.

To resume the log creation, click Resume log.

To clear the log, click Clear log.
Appendix B Configuring Tectia SSH Terminal GUI and Tectia Secure File Transfer GUI (Windows)

You can configure the Tectia user interface by clicking the User Interface Settings button on the toolbar, or by selecting the Edit → User Interface Settings option.

The different settings categories are visible on the left-hand side of the Settings dialog as a tree structure. Click on a branch to display the settings associated with it. You can change the settings by changing the selections displayed on the right-hand side of the Settings dialog. Note that some of the settings do not take effect until you save the settings and then open a new terminal or file transfer window, or start a new connection.

Note

Tectia Client includes two configuration tools:

- **Tectia Connections Configuration GUI** (behind the icon) is used to edit the connection settings

- **User Interface Settings** tool (behind the icon) is used to edit the Tectia SSH Terminal GUI and Tectia Secure File Transfer GUI.

For instructions on the connection configurations, see Section A.1.

B.1 Defining Global Settings
Global settings are common for all connections to remote host computers. Global settings are saved in the user profile directory ("%APPDATA%\SSH") with the filename `global.dat`.

![Figure B.1. The Global Settings page of the Settings dialog](image)

**B.1.1 Defining the Appearance**

The appearance of the application and the terminal window is configured using the **Appearance** page of the **Settings** dialog.
Figure B.2. The Appearance page of the Settings dialog

Office XP Look

Select the Office XP Look check box to change the way the menu bar and toolbar are displayed to match the visual style of Microsoft Office XP.

Terminal Settings

With the Terminal Settings options you can define how the terminal window works.

Paste on Right Mouse Click

Select this check box to enable fast copying of text on the terminal display. When you have this option selected, you can copy text simply by highlighting it and then paste it by clicking the right mouse button.

Scroll to Bottom on Output

Select this check box to have the terminal window scroll to the bottom whenever new text is output. If this option is not selected, you can view the terminal window without the windows scrolling to the bottom every time a new line of text is displayed. By default, this option is on.

Scrollbar Buffer Size

Type in this text box the number of lines that you want to collect into the scrollback buffer. The larger the value, the more you can scroll back the terminal display to view previous terminal output. The default value is 500 lines.
Open URLs on click

When this check box is selected, links in the terminal window can be opened by clicking them. This option is selected by default.

Window Caption

The Window Caption settings affect what is displayed in the title bar of the terminal window and the file transfer window.

Select the Display profile or hostname check box to have the profile name of the currently connected remote host computer displayed on the title bar if a profile is used. If a profile is not used, the hostname is displayed.

Window Layout

If you have created a connection profile with several windows open at the same time and saved the layout, all of the windows associated with the profile are normally opened when you select the profile. With the Window Layout option you can override this behavior.

Select the Open all windows in the profile check box to open all the windows associated with a profile when the profile is selected. If this option is not selected, the other windows open in their configured positions when you open new windows. By default, this option is on.

B.1.2 Selecting the Font and Terminal Window Size

The font used in the terminal window can be selected using the Font page of the Settings dialog. On the same page, you can also select if the size of the terminal window is fixed or adjusted automatically according to the font size.
Figure B.3. The Font page of the Settings dialog

Font

You can select the font to be used and its size. The new font settings affect the terminal window immediately when you click **OK**. To discard the changes, click **Cancel**.

Font Name

Select the desired font from the **Font Name** list. The list displays the non-proportional (fixed-width) fonts installed in your local computer. Note that proportional fonts are not suitable for the terminal window and therefore are not available for selection.

Font Size

Select the desired font size from the **Font Size** list. Note that the font size affects the size of the terminal window: the smaller the selected font, the smaller the terminal window. However, after changing the font size, the size of the terminal window can be modified, but the font size remains the selected one.

Fixed terminal window size

The size of the Tectia Terminal can be defined as fixed. By default, the terminal size is not fixed but adjusted according to the font size. The changes made to the fixed terminal window size setting become effective immediately when you click **OK**. To discard the changes, click **Cancel**.
Fix terminal window size and adjust font size automatically

Select this checkbox to use fixed terminal window size. You can define the width and the height of the window. The font size is then adjusted automatically to fit the window, and the font size selection becomes inactive, but you can still select the used font.

Width

Define the width of the fixed-size terminal window, in characters. The program suggests 80 characters by default.

Height

Define the height of the fixed-size terminal window, in characters. The program suggests 24 characters by default.

B.1.3 Selecting Colors

The colors used in the terminal window can be selected using the Colors page of the Settings dialog. The new color settings are active immediately when you click OK.

The color settings defined in Global Settings affect all connection profiles.

Note that changing the terminal colors does not affect what is already visible in the terminal window, but from this point onwards the text output will use the selected color scheme.

Figure B.4. The Colors page of the Settings dialog
Text Colors

The text colors affect the terminal window background color and the color of text in both a connected window and a disconnected window.

Foreground

Select the desired foreground color from the drop-down menu. Foreground color is used for text in a window that has a connection to a remote host computer. You can select from sixteen colors. Black is the default foreground color.

Background

Select the desired background color from the drop-down menu. You can select from sixteen colors. White is the default background color.

Selection

Use the drop-down menu to select the color that is used as the background color when selecting text with the mouse. You can select from sixteen colors. Aqua is the default selection color.

Disconnected

Use the drop-down menu to select the color that is used as the foreground color in a terminal window that has no connection to a remote host computer. You can select from sixteen colors. Gray is the default foreground color for a disconnected terminal window.

Cursor Color

Select the desired cursor color from the drop-down menu. You can select from sixteen colors. Navy is the default cursor color.

ANSI Colors

With ANSI control codes it is possible to change the color of text in a terminal window. With the ANSI Colors setting you can select to use this feature. Even if you disable ANSI colors, you can still select your favorite text and background colors to be used in the terminal window.

Select the Enable ANSI Colors check box to allow ANSI colors to be used in the terminal window. By default, ANSI colors are selected.

Reverse Colors

By reversing the display colors you can quickly change the display from positive (dark on light) to negative (light on dark) to improve visibility.

Select the Reverse Video check box to change the foreground color into background color and vice versa. This setting affects the whole terminal window when you click OK.

B.1.4 Defining Messages
On the **Messages** page of the **Settings** dialog you can configure default replies to standard messages that normally ask for user confirmation. The messages are listed under several categories.

![Figure B.5. Specifying which confirmation dialogs are displayed](image)

Each confirmation can be set to automatically accept (**Yes**) or reject (**No**) the action, or to ask the user for confirmation (**Ask**). By default all messages ask the user to confirm the action.

### B.1.5 Defining File Transfer Settings

The default settings of Tectia Secure File Transfer GUI can be configured using the **File Transfer** page of the **User Interface Settings** dialog. The new settings will affect subsequently started file transfer windows.

**Note**

The file transfer settings made here only affect the Tectia File Transfer GUI, not the SFTP conversion or command-line tools related to file transfer.
Figure B.6. The global File Transfer page of the Settings dialog

Options

The following options are available:

**Show Root Directory**

Select this check box to show the root directory in the file transfer window by default.

**Show Hidden Files**

Select this check box to show hidden files in the file transfer window by default.

**Check and Confirm Overwrite**

Select this check box if you want the file transfer utility to ask for confirmation when you try to transfer a file that already exists in the target system.

**Display Items by Using**

With this setting you can select the default view for the file transfer window by choosing one of the four possible views.

**Large Icons**

Select this option to display the file transfer file view as a Large Icons view. Each file and folder has a large icon associated with it, making for a clear and uncluttered display.
Small Icons

Select this option to display the file transfer file view as a Small Icons view. Each file and folder has a small icon associated with it. This makes it possible to display several times more items than the Large Icons view.

List

Select this option to display the file transfer file view as a List view. Each file and folder has a small icon associated with it, and the files and folders are displayed in one column.

Details

Select this option to display the file transfer folder view as a Details view. The files and folders are displayed with a small icon, their file name, file size, file type, their last modification date and attributes visible.

By clicking on the Name, Size, Type, Modified and Attributes sort bars located at the top of the File view, you can sort the files and folders based on their file name, file size, file type and the time they were last modified. Clicking the same sort option again reverses the sorting order.

Note that the sort function is not case-sensitive: uppercase text is sorted together with lowercase text.

The file type associations are derived from your local computer. If you have defined a new file type description for files with a certain file name extension, also the files in the remote computer are shown to be of that file type. This makes it easy to recognize particular file types also on the host computer.

If a file association is missing, use this application to open the file:

Tectia Client uses file type associations in the same way as Windows Explorer does. When you double-click a file in the file transfer window, it is opened using the application with which its file type has been associated.

All file types are not associated with any application. With this field you can define the application to use to open a file that has no file type association. The default application is Notepad, which is a reasonable choice for files containing text.

To change the default association for unknown file types, click the button next to the text field. A Select Application dialog is displayed, allowing you to select the desired application.

Formatting string for file time

In the formatting string field you can type a string that defines how the time and date stamps of the files are displayed in the file transfer window. The default value is %c, which means that the date and time will be shown in the format defined in the Windows country settings (locale).

To change the format of the time and date stamps, replace the default value with a string consisting of some of the following character combinations.
%a
  Abbreviated weekday name
%A
  Full weekday name
%b
  Abbreviated month name
%B
  Full month name
%c
  Date and time representation appropriate for locale
%d
  Day of month as decimal number (01 - 31)
%H
  Hour in 24-hour format (00 - 23)
%I
  Hour in 12-hour format (01 - 12)
%j
  Day of year as decimal number (001 - 366)
%m
  Month as decimal number (01 - 12)
%M
  Minute as decimal number (00 - 59)
%p
  Current locale's A.M. / P.M. indicator for 12-hour clock
%S
  Second as decimal number (00 - 59)
%U
  Week of year as decimal number, with Sunday as the first day of week (00 - 53)
%w
Weekday as decimal number (0 - 6; Sunday is 0)

%W
Week of year as decimal number, with Monday as the first day of week (00 - 53)

%x
Date representation for current locale

%X
Time representation for current locale

%y
Year without century, as decimal number (00 - 99)

%Y
Year with century, as decimal number

%z, %Z
Time-zone name or abbreviation; no characters if time zone is unknown

%%
Percent sign

**View Layout**

You can select how the file transfer window positions the local and remote view panes. The following options are available:

- Remote view on top, local view on bottom
- Remote view on right, local view on left
- Remote view on left, local view on right

Select the **Wide folder view in file bar** check box to show fewer buttons in the file bar, leaving more room for the favorite folders lists.

**B.1.6 Defining Advanced File Transfer Options**

On the **Advanced** page of the **Settings** dialog you can configure additional file transfer GUI options. The new settings will affect subsequently started file transfer windows.
Note

The file transfer settings made here only affect the Tectia File Transfer GUI, not the SFTP conversion or command-line tools related to file transfer.

Figure B.7. The advanced file transfer options

Configure advanced file transfer settings.

The following settings affect the file transfer:

**Force Lowercase**

Selecting this option forces lower case file names in file transfers.

**Preserve Original File Time**

Select this check box if you want the transferred files to retain their original time and date stamp values. If this option is not selected, the transferred files will be stamped with the time of the transfer.

Upload

The following settings affect the upload process:

**Do not change destination permissions**

Select this check box to preserve the file permissions on the server. If the transferred file overwrites an existing file, it will use the same file permissions as the original file. If the file is new, it will use the default permission mask of the server target directory.
Clear this check box to force new file permissions on uploaded files. Define the permissions in **New file permissions** and **New directory permissions** below.

**New file permissions**

Type the octal Unix file permission mask (as with the Unix `chmod` command) that is to be used as the value for uploaded files.

Octal (base-8) notation consists of three digits. The first digit specifies the permissions given to the owner of the file, the second digit specifies the permissions for the user group associated with the file, and the last digit specifies the permissions given to all other users.

Each of the three digits has one of the following values:

- **0**: No permissions.
- **1**: The file can be executed.
- **2**: The file can be written to.
- **3**: The file can be written to and executed. (2 + 1 = 3)
- **4**: The file can be read.
- **5**: The file can be read and executed. (4 + 1 = 5)
- **6**: The file can be read and written to. (4 + 2 = 6)
- **7**: The file can be read, written to and executed. (4 + 2 + 1 = 7)

For example, **644** (in symbolic notation `-rwx--r--r--`) specifies that the owner of the file has permission to read and write to the file, and the user group and others can only read the file.

**New directory permissions**

Type the octal Unix directory permission mask (as with the Unix `chmod` command) that is to be used as the value for uploaded directories.

The notation is the same as for **New file permissions**.

**File Transfer Send Window**

The following settings affect the file transfer process:

**Number of Buffers**

Type the number of buffers used in file transfer. The default value is 10.

**Buffer size**

Type the default buffer size (measured in kilobytes). The default value is 32 kilobytes.
Upload Locally Modified Remote Files

This selection affects how Tectia Client reacts if you locally edit a file stored in the remote host computer.

Yes

If you select this option, the locally modified file is uploaded to the remote host computer.

No

If you select this option, the locally modified file is not uploaded to the remote host computer.

Ask

If you select this option, Tectia Client asks you to decide if you want to upload a locally modified file.

B.1.7 Defining File Transfer Mode

The Mode page of the Settings dialog affects which files are transferred using ASCII mode.

Note

The file transfer settings made here only affect the Tectia File Transfer GUI, not the SFTP conversion or command-line tools related to file transfer.
File Transfer Mode

Select the default file transfer mode from the following options:

ASCII

By default all files will be transferred in ASCII mode.

Binary

By default all files will be transferred in binary mode.

Auto Select

The files using a file extension specified on the ASCII Extensions list will be transferred in ASCII mode. All other files will be transferred in binary mode.

ASCII Extensions

Files using a file extension specified in the ASCII Extensions list will be transferred using ASCII mode.

New

Click the New icon (at the top right-hand side of the ASCII Extensions list) to add a new file extension to the list. The keyboard shortcut for the New icon is the Ins key.

Note that you can use wildcard characters to specify the file extensions. The ? character matches any 1 character, and the * character matches any 0 or more characters. For example htm* would match both htm and html.

Delete

Select a file extension entry from the list and click the Delete icon (at the top right-hand side of the ASCII Extensions list) to remove the extension. The keyboard shortcut for the Delete icon is the Delete key.

B.1.8 Defining Local Favorites

On the Local Favorites page of the Settings dialog you can create a list of commonly used directories on your local computer. These favorites can then be easily selected from a drop-down menu in the File Transfer window.

Note

The file transfer settings made here only affect the Tectia File Transfer GUI, not the SFTP conversion or command-line tools related to file transfer.
Figure B.9. Creating a list of most commonly used directories

Favorite Folders

This list contains the favorite folders you have defined for your local computer. Initially the list contains your locally available drives. You can add, remove and sort the favorites by using the New, Delete, Up, and Down icons displayed above the list.

Home Folder

In the Home Folder field you can type the directory that is initially displayed in the local view pane of the file transfer window.

B.1.9 Defining Security Settings

The security settings can be configured using the Security page of the Settings dialog.
Appendix B Configuring Tectia SSH Terminal GUI and Tectia Secure File Transfer GUI (Windows)

Figure B.10. The Security page of the Settings dialog

Terminal Connections

The following options are available:

Empty Clipboard on Exit

Select this check box to remove anything that was recently copied using the cut and paste operations from the clipboard.

Empty Scrollback Buffer on Session Close

Select this check box to empty any remains of the terminal output from the scrollback buffer.

B.1.10 Printing

The print settings can be configured using the Printing page of the Settings dialog.
Figure B.11. The Printing page of the Settings dialog

**Printer Font**

Select the **Font Name** and **Font Size** to be used in the printed output. Any non-proportional font installed on your system can be selected.

**Margins (mm)**

Select the width of the blank border around the page in printed output. The margins for the top, bottom, left and right side of the page can all be specified individually. The default value for all margins is 10 millimeters (or 1 centimeter).

**Header & footer**

Select additional information to appear on the printed pages.

**Title** appears at the top left of the page and displays the title of the terminal window (for example `remotehost - Tectia Client`).

**Date** appears at the top right of the page and displays the date and time when the page was printed (for example `15 September 2003, 11:10`). The date and time format is the same as used in Windows.

**Page number** appears at the bottom right of the page (for example `Page 1 of 2`).

**Pass-through printing**

Pass-through printing allows the server to print on a client printer using terminal emulation codes.

In raw mode, Tectia Client sends the data to be printed as plaintext to the printer. In this mode, printing for example line graphics does not work.
If not in raw mode, Tectia Client sends the data to be printed to the printer as graphics. This is the default setting and should be used if there are no problems in printing. However, some older printers might not support printing graphics.

**Use raw mode**

Select this check box to pass the data to be printed to the printer in raw mode. If you experience printing problems, select or clear this selection as applicable.

### B.2 Using Command-Line Options

For some purposes it may be useful to operate the Tectia SSH Terminal GUI from the command line (command prompt).

The command-line syntax for the Tectia SSH Terminal GUI *(ssh-client-g3.exe)* is as follows:

```
ssh-client-g3 [-r] [-p port] [-u user] [-h host] [profile]
```

The command-line parameters have the following meanings:

- **-r**
  
  The `-r` option will reset all customizations made to the user interface (toolbars and menus). A confirmation dialog is displayed.

- **-p [port_number]**
  
  The `-p` option specifies the port number used for the connection. If this option is not specified, the port number defined in the default profile is used.

- **-u [user_name]**
  
  The `-u` option specifies the user name for the connection. If this option is not specified, the user name defined in the default profile is used.

- **-h [host_name]**
  
  The `-h` option specifies the hostname for the connection. If this option is not specified, the hostname defined in the default profile is used.

- **[profile]**
  
  If a profile is specified, it must be the last option on the command line. Any command-line parameters override the profile settings. If no profile is specified, the default profile is used.

- **-f**
  
  The `-f` (or `/f`) option starts the default SFTP file transfer profile.

For example, the following command would immediately start a connection to a host called `remotehost` and connect as `guest`. The port number is not specified, so the connection would use the port specified in the default profile.
Customizing the User Interface

The following command would immediately start a connection to remotehost using the settings defined in the profile file custom.ssh2.

```bash
ssh-client-g3 -h remotehost -u guest
```

If the host is not specified (using the `-h` option) and no profile is specified, the login dialog opens, automatically filled with the values specified on the command line.

For example, the following command would display the login dialog with the port number already defined as 222 and `guest` as the user name.

```bash
ssh-client-g3 -u guest -p 222
```

A command-line client `sshg3.exe` is also included in Tectia Client for Windows. It can be useful especially for creating scripts. For a description of the `sshg3.exe` syntax, see `sshg3(1)`.

Also several other command-line utilities are included in the Tectia Client installation. For more information, see Appendix C.

B.3 Customizing the User Interface

This section describes the options for modifying the graphical user interface.

B.3.1 Saving Settings

When you have made changes to the user interface settings, an asterisk (`*`) is displayed on the Tectia GUI title bar, after the name of the current settings file (for example: `default*`). This indicates that the changed settings are not yet permanent - they have not been saved yet.

If you want to make the changes permanent, you can save them for later use. Click the Save button on the toolbar, or select the File → Save Settings to save any changes you have made to your current settings.

The positions of the currently open terminal and file transfer windows can be saved separately with the File → Save Layout option. If you arrange your window positions and save the layout settings in the default settings file, the windows will be automatically positioned the way you prefer them when you next start the Tectia SSH Terminal GUI.

Note that by default all of the windows will be opened at once. This can be changed on the Appearance page of the Settings dialog so that the defined windows are opened only when necessary when you open new terminal and file transfer windows. See Section B.1.1.

If you spend a lot of effort specifying the settings, it is a good idea to create backup copies of the modified settings files (`ssh-broker-config.xml`, `global.dat`, and `*.ssh2`) and store them in a safe location. This way you will not have to create your personal settings again if your settings files are lost (for example because of a hardware failure).

Multiple Settings Files

You can save separate settings files for each remote host computer. This can be done by using the Profiles option. For more information on using profiles, see Section A.1.3.
B.3.2 Loading Settings

It is easy to take a previously saved profile into use. Select the Profiles option on the Profiles toolbar, or from File → Profiles, and you will see a menu of previously saved profiles. Click on a profile name, and a connection using the profile settings is started immediately.

Note that this also works when you are already connected to a remote host computer. Clicking the profile name will start a new, separate connection.

Another way to load the settings for a particular connection is to double-click the settings file name for example in Windows Explorer. When Tectia Client is installed, files with the extension .ssh2 are associated with the Tectia software. This means that you can start Tectia Client with any settings file loaded by double-clicking the settings file.

If you regularly connect to several remote host computers, you can create shortcuts to the corresponding settings files for example on the Windows desktop. This way you can quickly open the desired connection with the relevant settings already defined, just by clicking on an icon on the desktop.

B.3.3 Customize Dialog

Select View → Customize to modify the menu options, toolbars layout, keyboard mapping, menu settings, and general preferences. Note that you can have only one terminal window open when using the Customize option.

![Customize dialog](image)

Figure B.12. Use the Customize dialog to modify the user interface settings

Click on the tabs at the top of the dialog to switch between different pages:

Commands tab

Select the Commands tab to move individual menu options. Select the menu category from the list on the left, and then use the mouse to drag menu options into the menus or toolbars displayed in the Tectia SSH Terminal GUI.
Toolbars tab

On the Toolbars tab, select those toolbars that you want displayed in the Tectia SSH Terminal GUI.

![Customize Toolbars](image)

**Figure B.13. Selecting toolbars**

- **Reset**: Select the toolbar that you want to restore to its initial settings and click the Reset button to discard the changes you have made.
- **Reset All**: Click the Reset All button to discard the changes you have made to all of the toolbars.
- **Show Text Labels**: Select either the Profiles or the Toolbar option and then select the Show text labels check box to display text labels on these toolbars. Text labels clarify the toolbar icons, but also take up space.

Keyboard tab

Select the Keyboard tab to define shortcut keys for the menu commands.

![Customize Keyboard](image)

**Figure B.14. Customizing the keyboard**

Use the Category menu to select the category of the accelerator key you want to modify. The categories are based on the menu hierarchy.
Use the **Commands** menu to select a specific command from the selected category.

The **Description** box displays a brief description of the currently selected command.

Use the **Set Accelerator for** menu to select the profile that you want to associate with the current keyboard configuration.

The **Current Keys** field shows the currently assigned accelerator keys.

Click on the **Press New Shortcut Key** field to activate it. Then press the combination of keys on the keyboard that you want to associate with the currently selected command.

- **Assign**: Click **Assign** to add the definition from the Press New Shortcut Key field to the Current Keys field.
- **Remove**: Select a key assignment from Current Keys field and click **Remove** to delete it.
- **Reset All**: Click **Reset All** to undo all your changes and reset the keyboard assignments. A confirmation dialog will be displayed.

**Menu** tab

Select the **Menu** tab to define the menu settings.

![Customizing the menus](image)

**Figure B.15. Customizing the menus**

- **Application Frame Menus**: Select the menu setup you want to change from the **Show Menus For** drop-down menu. By default, only **Default Menu** is available for editing.

  Click **Reset** to reset the menus to their original configuration.

- **Menu Animations** drop-down menu to select the type of menu animations. The available options are **None**, **Unfold**, **Slide**, and **Fade**.

- **Menu Shadows** check box to display shadows under open menus.

- **Context Menus**: Use the **Select Context Menu** drop-down menu to display any of the shortcut (or popup) menus:
• *File Local Menu 1* is displayed in the local view of the file transfer window when you do not have a file selected.

• *File Local Menu 2* is displayed in the local view of the file transfer window when you have a file selected.

• *File Remote Menu 1* is displayed in the remote view of the file transfer window when you do not have a file selected.

• *File Remote Menu 2* is displayed in the remote view of the file transfer window when you have a file selected.

• *Terminal Popup menu* is displayed when you right-click in the terminal window.

You can click the Commands tab and drag menu options into the shortcut menus (and remove items from the shortcut menus by dragging them from the menu).

• **Reset**: Click **Reset** to reset the menus to their original configuration.

**Options** tab

Select the **Options** tab to change general user-interface options.

![User Interface Options](image)

**Figure B.16. Customizing general user-interface options**

Select the **Show ScreenTips on Toolbars** check box to display a short help text when you place the mouse pointer over a toolbar button.

Select the **Show Shortcut Keys in ScreenTips** check box to see the possible keyboard shortcut displayed in addition to the short help text.

Select the **Large Icons** check box to display large toolbar icons.

Select the **Look 2000** check box to enable Windows-2000-style features in the user interface. This option affects mainly the style of the toolbar handles.
B.3.4 Customizing Toolbars

Tectia Client has a dynamic user interface where you can select the position of the toolbars.

**Note**

The File bar displayed in the file transfer window is dynamically created, and therefore it cannot be customized.

You can use the mouse to grab the toolbars by their handles (located on the left-hand end of each toolbar) and move them around the Tectia SSH Terminal GUI. You can have the toolbars floating freely in the window, or anchor them to the top, bottom or either side of the window.

It also possible to move the individual menu options. This can be done using the **Commands** page of the Customize dialog (see Section B.3.3).

Changes become permanent even if you do not save the settings, but you can cancel the changes and reset the view to the default settings.

To undo the changes, select **View → Reset Toolbars**. A confirmation dialog opens, asking if you really want to discard the changes. If you select **Yes**, the toolbars and menus will return to their original configuration.

B.4 Logging a Session

Tectia Client can log the terminal output of your session into a text file. The feature can be enabled via the **Tectia SSH Terminal GUI**.

To start recording your session to a text file, select **File → Log Session**. In the **Save As** dialog box that opens, define the file you want the session to be logged into. You can either enter the name of a new file, or select an existing file.

If you choose to log the session into an existing file, a **File already exists** message opens. To overwrite the existing file, click **Yes**. To append the session log to the end of the existing file, click **No**.
Appendix C Command-Line Tools and Man Pages

Tectia Client is shipped with several command-line tools. Their functionality is briefly explained in the following appendices.

On Unix, the same information is available on the following manual pages:

- `ssh-broker-g3(1)`: Connection Broker – Generation 3
- `ssh-broker-ctl(1)`: Connection Broker control utility
- `ssh-troubleshoot(8)`: utility for collecting system information for troubleshooting purposes
- `sshg3(1)`: Secure Shell terminal client – Generation 3
- `scpg3(1)`: Secure Shell file copy client – Generation 3
- `sftpg3(1)`: Secure Shell file transfer client – Generation 3
- `ssh-translation-table(1)`: Secure Shell file transfer translation table
- `ssh-keygen-g3(1)`: authentication key pair generator
- `ssh-keyfetch(1)`: utility for downloading server host keys
- `ssh-cmpclient-g3(1)`: certificate CMP enrollment client
- `ssh-scepclient-g3(1)`: certificate SCEP enrollment client
- `ssh-certview-g3(1)`: certificate viewer
- `ssh-ekview-g3(1)`: external key viewer
For information on the command-line options of Tectia SSH Terminal GUI (ssh-client-g3.exe) on Windows, see Section B.2.

For a description of the Connection Broker configuration file options, see ssh-broker-config(5).
ssh-broker-g3

ssh-broker-g3 — Tectia Connection Broker - Generation 3

Synopsis

Description

ssh-broker-g3 (ssh-broker-g3.exe on Windows) is a component of Tectia Client. It handles all cryptographic operations and authentication-related tasks for Tectia Client and for the client programs sshg3, scp3, sftp3, and ssh-client-g3.exe (on Windows only).

ssh-broker-g3 uses the Secure Shell version 2 protocol to communicate with a Secure Shell server.

You can start the Connection Broker manually by using the ssh-broker-g3 command. This starts ssh-broker-g3 in the background and all following uses of sshg3, sftp3, or scp3 will connect via this instance of the Connection Broker instead of starting a new Broker session.

If a command-line client (sshg3, sftp3, or scp3) is started when the Connection Broker is not running in the background, the client starts the Broker in run-on-demand mode. In this mode, ssh-broker-g3 will exit after the last client has disconnected.

If there is an ssh-broker-g3 process running in the run-on-demand mode, and the Connection Broker is started from the command line, the new ssh-broker-g3 process sends a message to the old ssh-broker-g3 process to change from the run-on-demand mode to the background mode, keeping the Broker running after the clients disconnect.

The status of the running Connection Broker can be checked using the ssh-broker-ctl and ssh-broker-gui utilities.

Authentication

The Connection Broker operates automatically as an authentication agent, storing user's public keys and forwarding the authentication over Secure Shell connections. Key pairs can be created with ssh-keygen-g3.

The Connection Broker can also serve OpenSSH clients as an authentication agent.

The public key pairs used for user authentication are by default stored in the $HOME/.ssh2 directory (%APPDATA%\SSH\UserKeys on Windows). See the section called “Files” for more information.

The Connection Broker automatically maintains and checks a database containing the public host keys used for authenticating Secure Shell servers. When logging in to a server host for the first time, the host's public key is stored in the user's $HOME/.ssh2/hostkeys directory (%APPDATA%\SSH\HostKeys on Windows). See the section called “Files” for more information.
Options

The most important options of ssh-broker-g3 are the following:

-a, --broker-address=ADDR

Listens to Connection Broker connections on a local address ADDR.

-D, --debug=LEVEL

Sets the debug level string to LEVEL.

-f, --config-file=FILE

Reads the Connection Broker configuration file from FILE instead of the default location.

-l, --debug-log-file=FILE

Dumps debug messages to FILE.

--pid-file=FILE

Stores the process ID of the Connection Broker to FILE.

--exit

Make the currently running Connection Broker exit. This will terminate all connections.

--reconfig

Re-reads the configuration file (ssh-broker-config.xml) and takes it into use.

-V, --version

Displays program version and exits.

-h, --help

Displays a short summary of command-line options and exits.

Environment Variables

The following optional environment variables are required in certain situations:

SSH_SECSH_BROKER=ADDRESS

This variable defines an address to a separate Tectia Connection Broker process to which a connection is made.

This variable becomes necessary to define the location of the Connection Broker process, if you are running it from a non-default location, or using a userID other than that of the ssh-broker-g3 process owner.
Files

ssh-broker-g3 uses the following files:

$HOME/.ssh2/ssh-broker-config.xml

This is the user-specific configuration file used by ssh-broker-g3 (and sshg3, scp3, and sftpg3). The format of this file is described in ssh-broker-config(5). This file does not usually contain any sensitive information, but the recommended permissions are read/write for the user, and not accessible for others.

On Windows, the user-specific configuration file is located in %APPDATA%\SSH\ssh-broker-config.xml.

$HOME/.ssh2/random_seed

This file is used for seeding the random number generator. It contains sensitive data and its permissions should be read/write for the user and not accessible for others. This file is created the first time the program is run and it is updated automatically. You should never need to read or modify this file.

On Windows, the random seed file is located in %APPDATA%\SSH\random_seed.

$HOME/.ssh2/identification

This file contains information on public keys and certificates used for user authentication when contacting remote hosts.

With Tectia Client G3, using the identification file is not necessary if all user keys are stored in the default directory and you allow all of them to be used for public-key and/or certificate authentication. If the identification file does not exist, the Connection Broker attempts to use each key found in the $HOME/.ssh2 directory. If the identification file exists, the keys listed in it are attempted first.

The identification file contains a list of private key filenames each preceded by the keyword IdKey (or CertKey). An example file is shown below:

<table>
<thead>
<tr>
<th>IdKey</th>
<th>mykey</th>
</tr>
</thead>
</table>

This directs the Connection Broker to use $HOME/.ssh2/mykey when attempting login using public-key authentication.

The files are by default assumed to be in the $HOME/.ssh2 directory, but also a path to the key file can be given. The path can be absolute or relative to the $HOME/.ssh2 directory. If there is more than one IdKey, they are tried in the order that they appear in the identification file.

On Windows, the identification file is located in %APPDATA%\SSH\identification. Key paths in the file can be absolute or relative to the %APPDATA%\SSH directory. The default user key directory is %APPDATA%\SSH\UserKeys and the default user certificate directory is %APPDATA%\SSH\UserCertificates.

$HOME/.ssh2/hostkeys

© 1995–2021 SSH Communications Security Corporation

Tectia® Client 6.4 User Manual
This is the user-specific default directory for storing the public keys of server hosts. You are prompted to accept new or changed keys automatically when you connect to a server, unless you have set `strict-host-key-checking` to `yes` in the `ssh-broker-config.xml` file. You should verify the key fingerprint before accepting new or changed keys.

When the host key is received during the first connection to a remote host (or when the host key has changed) and you choose to save the key, its filename is stored by default in hashed format. The hashed host key format is a security feature to make address harvesting on the hosts difficult.

The storage format can be controlled with the `filename-format` attribute of the `known-hosts` element in the `ssh-broker-config.xml` configuration file. The attribute value must be `plain` or `hash` (default).

If you are adding the keys manually, the keys should be named with `key_<port>_<host>.pub` pattern, where `<port>` is the port the Secure Shell server is running on and `<host>` is the hostname you use when connecting to the server (for example, `key_22_alpha.example.com.pub`).

If both hashed and plain-text format keys exist, the hashed format takes precedence.

Note that the identification is different based on the host and port the client is connecting to. For example, the short hostname `alpha` is considered different from the fully qualified domain name `alpha.example.com`. Also a connection with an IP, for example `10.1.54.1`, is considered a different host, as is a connection to the same host but different port, for example `alpha.example.com#222`.

On Windows, the user-specific host key files are located in `%APPDATA%\SSH\HostKeys`.

For more information on host keys, see Section 4.2.

$HOME/.ssh2/hostkeys/salt

This is the initialization file for hashed host key names.

On Windows, the salt file is located in `%APPDATA%\SSH\HostKeys\salt`.

/opt/tectia/share/auxdata/ssh-broker-ng/ssh-broker-config-default.xml

This is the configuration file used by `ssh-broker-g3` (and `sshg3`, `scpg3`, and `sftpg3`) that contains the factory default settings. It is not recommended to edit the file, but you can use it to view the default settings. The format of this file is described in `ssh-broker-config(5)`.

On Windows, the default configuration file is located in `<INSTALLDIR>\SSH Tectia AUX\ssh-broker-ng\ssh-broker-config-default.xml`.

/etc/ssh2/ssh-broker-config.xml

This is the global (system-wide) configuration file used by `ssh-broker-g3` (and `sshg3`, `scpg3`, and `sftpg3`). The format of this file is described in `ssh-broker-config(5)`.

On Windows, the global configuration file is located in `<INSTALLDIR>\SSH Tectia Broker\ssh-broker-config.xml`.

© 1995–2021 SSH Communications Security Corporation
/etc/ssh2/hostkeys

If a host key is not found in the user-specific $HOME/.ssh2/hostkeys directory, this is the next location to be checked for all users. Host key files are not automatically put here but they have to be updated manually by the system administrator (root).

If the administrator obtains the host keys by connecting to each host, the keys will be by default in the hashed format. In this case, also the administrator’s $HOME/.ssh2/hostkeys/salt file has to be copied to the /etc/ssh2/hostkeys directory.

On Windows, the system-wide host key files are by default located in:

"C:\Documents and Settings\All Users\Application Data\SSH\HostKeys" on pre-Vista Windows.

"C:\ProgramData\SSH\HostKeys" on Windows Vista and later Windows versions.

/etc/ssh2/hostkeys/salt

This is the initialization file for hashed host key names. The file has to be copied here manually by the same administrator that obtains the host keys.

On Windows, the salt file for all users is by default located in:

"C:\Documents and Settings\All Users\Application Data\SSH\HostKeys\salt" on pre-Vista Windows.

"C:\ProgramData\SSH\HostKeys\salt" on Windows Vista and later Windows versions.

/etc/ssh/ssh_known_hosts

This is the default system-wide file used by OpenSSH clients for storing the public key data of known server hosts. It is supported also by Tectia Client.

If a host key is not found in the user-specific $HOME/.ssh/known_hosts file, this is the next location to be checked for all users.

The ssh_known_hosts file is never automatically updated by Tectia Client, since they store new host keys always in the Tectia user-specific directory $HOME/.ssh2/hostkeys.

$HOME/.ssh/known_hosts

This is the default user-specific file used by OpenSSH clients for storing the public key data of known server hosts. The known_hosts file is supported also by Tectia Client.

The known_hosts file contains a hashed or plain-text format entry of each known host key and the port used on the server, in case it is non-standard (other than 22). For more information on the format of the known_hosts file, see the OpenSSH sshd(8) man page.

The known_hosts file is never automatically updated by Tectia Client, since they store new host keys always in the Tectia directory $HOME/.ssh2/hostkeys.
$HOME/.ssh2/authorized_keys (on the server host)

This directory is the default location used by Tectia Server for the user public keys that are authorized for login.

On Tectia Server on Windows, the default directory for user public keys is %USERPROFILE% \.ssh2\authorized_keys.

$HOME/.ssh2/authorization (on the server host)

This is the default file used by earlier versions of Tectia Server (sshd2) that lists the user public keys that are authorized for login. The file can optionally be used with Tectia Server G3 (ssh-server-g3) as well.

On Tectia Server on Windows, the authorization file is by default located in %USERPROFILE% \.ssh2\authorization.

For information on the format of this file, see the ssh-server-g3(8) man page.

$HOME/.ssh/authorized_keys (on the server host)

This is the default file used by OpenSSH server (sshd) that contains the user public keys that are authorized for login.

For information on the format of this file, see the OpenSSH sshd(8) man page.
ssh-broker-ctl

ssh-broker-ctl — Tectia Connection Broker control utility

Synopsis

ssh-broker-ctl command
[options...]

Description

ssh-broker-ctl (ssh-broker-ctl.exe on Windows) is a control utility for the Connection Broker (ssh-broker-g3). It can be used, for example, to view the status of the Connection Broker, to reconfigure or stop the Connection Broker, to manage keys and certificates, and to manage connections.

Options

The following general options are available:

-a, --broker-address ADDRESS

Defines an address to a separate Tectia Connection Broker process to which a connection is made.

The same effect can be achieved by defining a Connection Broker address with environment variable SSH_SECSH_BROKER.

Tip

If you are running ssh-broker-ctl using a userID other than that of the ssh-broker-g3 process owner, the -a option must be given so that ssh-broker-ctl knows where to connect. In this case, you must also run ssh-broker-ctl as a privileged user (root).

For example, when user SSHBRKR owns the ssh-broker-g3 process, run the ssh-broker-ctl with commands:

```bash
# ssh-broker-ctl -a /tmp/ssh-SSHBRKR/ssh-broker status -s
# ssh-broker-ctl -a /tmp/ssh-SSHBRKR/ssh-broker status --pid
# ssh-broker-ctl -a /tmp/ssh-SSHBRKR/ssh-broker list-connections
```

-D, --debug STR

Defines the debug level.

-e, --charset=CS

Defines the character set to be used in the output. The supported character sets are utf8, iso-8895-1, latin1, iso-8859-15, latin9, and ascii.
-q, -quiet

Defines that little or no output is to be displayed, depending on the command.

-s, -short

Defines that a shorter, more machine readable, output format is to be used.

--time-format=FMT

Defines the time format to be used in the output. The default depends on the system locale settings.

-v, -verbose

Defines that more information, if available, is to be output.

-V, --version

Displays the version string.

-w, --wide

Defines that the output will not be truncated, even if it means long lines.

-h, --help

Displays a context-sensitive help text on command-line options. Help is available also on specific commands. For example, to get help on the status command, run:

$ ssh-broker-ctl status --help

Commands

Note

For a detailed description of the command options, use the command-specific --help option.

**ssh-broker-ctl** accepts the following commands:

**add-certificate [options] <certificate-file>**

Adds the given X.509 sub-CA certificate to the Connection Broker certificate cache. The certificate can be used in certificate validations but it is not stored permanently. Restarting the Connection Broker will remove the certificate.

**add-crl [options] <crl-file>**

Adds the given X.509 CRL to the Connection Broker CRL cache. The CRL can be used in certificate validations but it is not stored permanently. Restarting the Connection Broker will remove the CRL.

**add-key filename**

Adds a new private key from the given file name. The private key is not stored permanently in the configuration. Stopping the Connection Broker will remove the key.
add-provider type parameter

Registers a key provider to the Connection Broker. The type option is one of the supported provider
types and the parameter option is a parameter string specific to the provider type.

For a list of the supported key provider types and the corresponding parameter formats, use the
command-specific --help option.

auth-handler [options]

 Registers itself as the default authentication form handler. All authentication prompts for clients that
are unable to handle them (mostly SOCKS proxy and other tunnels) are directed to this client.

For a list of the supported key provider types and the corresponding parameter formats, use the
command-specific --help option.

close-channel channel-id ...

Closes the defined channel. You can also enter multiple channel-IDs to close several channels.

close-connection connection-id ...

Closes the defined connection. You can also enter multiple connection-IDs to close several
connections.

close-tunnel-listener tunnel-id ...

Closes open tunnel listener. Tunnel id is either the id number returned by ssh-broker-ctl list-tunnel-
listeners command or a listen address and port pair separated by a colon. If the listen address is
omitted, local listeners (127.0.0.1) are selected. As an example, the following command closes the
listener with id 7, and the ones listening at 168.192.0.15 port 1234 and 127.0.0.1 port 2112:

```
$ ssh-broker-ctl ctl 7 168.192.0.15:1234 :2112
```

config-value [options] path

Retrieves configuration values from the Connection Broker based on the defined path and displays
them.

connection-status [--show-channels][--write-hostkey=FILE] connection-id

Displays a detailed connection status for the connection ID (the numeric identifier shown by the list-
connections) command.

connector [options] [enable|disable]

Enables and disables the Connector functionality in the Connection Broker. Without parameters
prints the current state.

disconnect-client client-id

Disconnects a Connection Broker client process.

Sets the Connection Broker debug level to the defined level. If no debug-level parameter is given here, the current debug level is not changed.

keylog [--remove] [--all] [--update <key-id|key-hash>] [--init] [--uninit] [--close] [-v, --verbose] [key-id|key-hash|hostname]

Keylog is used to manage uploaded public keys and to display a log of them. The Keylog does not store the public keys, it only stores information about the keys and the hosts where the keys have been uploaded to. The information can be used to manage the keys at a later stage, for example, to track hosts where a key has been uploaded to. The keylog is not on by default, it must be enabled first.

Without the options, displays a list of the uploaded keys. If a key or a hostname is specified, only the selected keys are displayed.

key-passphrase [--all] [--clear] [--passphrase-file=filename] [--passphrase-string=passphrase] [key-id|key-hash]

Prompts the user's private-key passphrase or PIN code.

key-upload [options] key [user[@]server[#port]]

Uploads the selected key (key can be a key ID number, a public key hash or a file name) into the authorized keys directory or file on the server, depending on the automatically detected upload method. After the operation, the key can be used in public-key authentication to log in to the server without a password. If the keylog is enabled, the command prompts for a keylog passphrase (if needed), and information about the public keys is stored in the key upload log.

list-connections [-c, --show-channels] [-s, --short] [--client-pid=PID] [--disconnected]

Displays a list of the currently open connections together with connection parameters and traffic statistics. Displays also the connection ID which can be used with other commands to identify the connection.

list-channels [-s, --short]

Displays a list of the currently open connection channels, together with channel type and traffic statistics. Displays also the channel ID which is used by other commands to identify the connection.

list-clients [-c, --show-channels] [-s, --short] [--all]

Displays a list of the currently connected client processes.

list-keys [-s, --short] [--extra-certificate] [--provider=ID]

Displays a list of the user's private keys, together with the basic key attributes such as the key type, size, and possible file name or key provider information. Outputs also the fingerprint and the identifier of the key. The identifier is used by other Connection Broker commands to identify the private key.
list-profiles [-s, --short] [-v, --verbose] [name ...]

Displays a list of connection profiles in the Connection Broker. Shows the profile name and basic connection settings, such as the host and the user name. If profile names are given, only those profiles are listed.

list-providers [ provider ...]

Displays a list of the key providers in the Connection Broker. If one or more provider names or ID numbers are given, only those providers will be listed. The provider name can be either a full provider name or a prefix.

list-tunnel-listeners [options]

Displays a list of the currently active tunnel listeners (also called port forwards).

open-tunnel-listener [options] listen-port [user@]server [port] [dst-host] [dst-port]

Opens a tunnel listener, similar to sshg3 -L and -R options. The difference is that ssh-broker-ctl will exit after the tunnel is opened. The tunnel status can be viewed with ssh-broker-ctl list-tunnel-listeners command and the tunnel can be closed with ssh-broker-ctl close-tunnel-listener command.

In local mode (default), the listener is opened to localhost listen-port. All connections will be tunneled through server and from there to the final destination address and port. Tunnel types socks and socks-proxy do not require destination information as it will be obtained from SOCKS client. Tunnel types tcp, ftp and local require destination information.

pkcs10-sign [options] key-id [subject-name]

Signs a PKCS#10 certificate request with the given key. The key-id can be either a key id or a key hash. The subject name parameter is required unless the template option is used. If the subject name is not a valid distinguished name, it will be wrapped automatically into a common name component. For example, a subject name string My Name will be converted to CN=My Name.

probe-key [options] address#port

Probes for a Secure Shell server hostkey. Connects to the given address and port (defaults to 22) and displays the server's public key or certificate.

reload

Rereads the Connection Broker configuration file.

remove-key [options] key-id

Removes a private key permanently.

remove-provider [--all] provider-id

Removes a key provider from the Connection Broker.
start

Starts the Connection Broker in daemon mode if it is not already running.

start-gui

Starts the Connection Broker GUI process unless it is already running.

status [-s, --short] [-q, --quiet] [-pid] [-all]

Without parameters, displays short statistics and a configuration summary for the currently running Connection Broker process.

stop

Stops the Connection Broker.

validate-certificate [options] <certificate-file>

Validates the given X.509 certificate. If a host name is given, also checks if the certificate would be accepted as a host certificate for the host.

view-key [-s, --short] [-v, --verbose] [-clear] [-write-key= file] key-id

Displays information on the defined key. If the key has certificates, a short summary of them is also shown.
ssh-troubleshoot

ssh-troubleshoot — tool for collecting system information

Synopsis

ssh-troubleshoot [options] [command [command-options]]

Description

ssh-troubleshoot (ssh-troubleshoot.cmd on Windows) is a tool for collecting information on the operating system (its version, patches, configuration settings, installed software components, and the current environment and state) and on the Tectia installation (installed product components and versions, their state, and the global and user-specific configurations).

The collected information will be stored in a file named ssh_troubleshoot_<host>_<date>_<time>.tar on Unix and ssh_troubleshoot_.log on Windows. Send the file to the SSH technical support for analysis to help in troubleshooting situations.

To get all necessary information, run the command as an administrator, because it might need root access to some directories.

Options

Enter each option separately, they cannot be combined. The following options are available:

- **-d, --debug LEVEL**

  Sets the debug level string to 

  LEVEL.

- **-k, --keep-going**

  Defines that the data collecting is continued as long as possible, even after errors are encountered. Not supported on Windows.

- **-o, --output FILENAME**

  Defines a non-default output file for storing the collected data. Not supported on Windows.

  If FILENAME is ‘-‘, the collected data is added to the standard output. The default output file is created in a temporary archive directory and stored as ssh-troubleshoot-data-<hostname>-<timestamp>.tar. The timestamp is in format: yyyy-mm-dd-hhmmUTC.

- **-u, --user USERNAME**

  Defines another user for the info command, the default is the current user. This affects the home directory from which the user-specific Tectia configuration files are fetched. Not supported on Windows.
-q, --quiet

Suppresses detailed reporting about the command progress, reports only errors.

-h, --help

Displays this help text.

## Commands

**ssh-troubleshoot** accepts the following command:

**info**

Gathers information about the system configuration. The collected data will be stored as a **tar** file on Unix or a **log** file on Windows.

**Options:**

--include-private-keys

Collects everything from the specified user's configuration directories, including the private keys. By default, the private keys nor unrecognized files are not included in the result data. This option is not supported on Windows.
sshg3

sshg3 — Secure Shell terminal client - Generation 3

Synopsis

```
sshg3 [options...] profile [[user@] host [#port] [command]
```

Description

sshg3 (sshg3.exe on Windows) is a program for logging in to a remote machine and executing commands on a remote machine. sshg3 provides secure, encrypted communication channels between two hosts over an unsecured network. It can be used to replace the unsecured rlogin, rsh, and telnet programs. Also X11 connections and arbitrary TCP/IP ports can be forwarded over secure channels with sshg3.

To connect to a remote host using sshg3, give either the name of a connection profile defined in the ssh-broker-config.xml file (profile) or the IP address or DNS name of the remote host, optionally with the remote user name and the port of the Secure Shell server ([user@]host[#port]). If no user name is given, the local user name is assumed. If no port is given, the default Secure Shell port 22 is assumed. The remote host must be running a Secure Shell version 2 server.

sshg3 acts as a Connection Broker client and launches the actual Connection Broker process, ssh-broker-g3 as a transport (in run-on-demand mode), or uses an already running Connection Broker process. The Connection Broker will ask the user to enter a password or a passphrase if they are needed for authentication. Connection Broker uses the configuration specified in the ssh-broker-config.xml file.

When the user's identity has been accepted by the server, the server either executes the given command, or logs in to the machine and gives the user a normal shell. All communication with the remote command or shell will be automatically encrypted.

If no pseudo-tty has been allocated, the session is transparent and can be used to securely transfer binary data.

The session terminates when the command or shell on the remote machine exits and all X11 and TCP/IP connections have been closed. The exit status of the remote program is returned as the exit status of sshg3.

Agent Forwarding (Unix)

sshbroker-g3 acts as an authentication agent, and the connection to the agent is automatically forwarded to the remote side unless disabled in the ssh-broker-config.xml file or on the sshg3 command line (with the -a option).

X11 Forwarding

If the user is using X11 (the DISPLAY environment variable is set), the connection to the X11 display can be automatically forwarded to the remote side in such a way that any X11 programs started from the
shell (or command) will go through the encrypted channel, and the connection to the real X server will be made from the local machine. The user should not manually set DISPLAY. X11 connection forwarding can be allowed in the ssh-broker-config.xml file or on the sshg3 command line (with the +x option). By default, X11 forwarding is disabled.

The DISPLAY value set by sshg3 will point to the server machine, but with a display number greater than zero. This is normal, and happens because sshg3 creates a "proxy" X server on the server machine for forwarding the connections over the encrypted channel.

sshg3 will also automatically set up the Xauthority data on the server machine. For this purpose, it will generate a random authentication cookie, store it in the Xauthority data on the server, and verify that any forwarded connections carry this cookie and replace it with the real cookie when the connection is opened. The real authentication cookie is never sent to the server machine (and no cookies are sent in the plain).

TCP Port Forwarding

Forwarding of arbitrary TCP/IP connections over the secure channel can be specified either in the ssh-broker-config.xml file or on the sshg3 command line (with the -L and -R options).

Options

Command-line options override the settings in the ssh-broker-config.xml file if the same option has been configured in both places. The following options are available:

-a, --no-agent-forwarding

Disables authentication agent forwarding. In the factory settings, agent forwarding is enabled.

+a

Enables authentication agent forwarding. In the factory settings, agent forwarding is enabled, but it can be denied in the Connection Broker configuration file, in which case users cannot enable it on the command-line and this +a will be ignored.

-B, --batch-mode

Uses batch mode. Fails authentication if it requires user interaction on the terminal.

Using batch mode requires that you have previously saved the server host key on the client and set up a non-interactive method for user authentication (for example, host-based authentication or public-key authentication without a passphrase).

-C

Disables compression from the current connection.

+C

Enables zlib compression for this particular connection.
-c, --ciphers=LIST

Sets the allowed ciphers to be offered to the server. List the cipher names in a comma-separated list. For example:

```
--ciphers seed-cbc@ssh.com,aes256-cbc
```

Enter help as the value to view the currently supported cipher names.

-D, --debug=LEVEL

Sets the debug level. LEVEL is a number from 0 to 99, where 99 specifies that all debug information should be displayed. This should be the first argument on the command line.

**Note**

Option -D only applies on Unix. On Windows, instead of this command-line tool, use the Connection Broker debugging options -D, -l.

**Note**

The debug level can be set only when the sshg3 command starts the Connection Broker. This option has no effect in the command if the Connection Broker is already running.

-e, --escape-char=CHAR

Sets escape character (none: disabled, default: ~).

-f, --fork-into-background

Forks into background mode after authentication (Unix only). Use this option with tunnels and remote commands. Implies -S (unless a command is specified). When tunnels have been specified, this option makes sshg3 stay in the background, so that it will wait for connections indefinitely. sshg3 has to be killed to stop listening.

-g, --gateway

Gateways ports, which means that also other hosts may connect to locally forwarded ports. This option has to be specified before the "-L" option. Note the logic of + and - in this option.

+g

Does not gateway ports. Listens to tunneling connections originating only from the localhost. This is the default value. Note the logic of + and - in this option.

-i FILE

Defines that private keys defined in the identification file are used for public-key authentication.

-K, --identity-key-file=FILE

Defines that the given key file of a private key or certificate is used in user authentication. The path to the key file is given in the command.
If the file is a private key, it will be read and compared to the keys already known by the Connection Broker key store. If the key is not known, it will be decoded and added to the key store temporarily. If the file is a certificate and Connection Broker knows a matching private key, it will be used. Both the certificate and the private key can be given using multiple -k options on command line.

-L, --localfwd [protocol/] [listen-address:] listen-port:dst-host:dst-port

Forwards a port on the local (client) host to a remote destination host and port.

This allocates a listener port (listen-port) on the local client. Whenever a connection is made to this listener, the connection is tunneled over Secure Shell to the remote server and another connection is made from the server to a specified destination host and port (dst-host:dst-port). The connection from the server onwards will not be secure, it is a normal TCP connection.

Giving the argument protocol enables protocol-specific forwarding. The protocols implemented are tcp (default, no special processing), ftp (temporary forwarding is created for FTP data channels, effectively securing the whole FTP session), and socks.

With the socks protocol, the syntax of the argument is ”-L socks/[listen-address:]listen-port”. When this is set, Tectia Client acts as a SOCKS server for other applications, creating forwards as requested by the SOCKS transaction. This supports both SOCKS4 and SOCKS5.

If listen-address is given, only that interface on the client is listened. If it is omitted, all interfaces are listened.

-l, --user=USERNAME

Logs in using this user name.

-m, --macs=LIST

Sets the allowed MACs to be offered to the server. List the MAC names in a comma-separated list. For example:

```
--macs hmac-sha1-96,hmac-md5,hmac-md5-96
```

Enter help as the value to view the currently supported MAC names.

-u, --kexs=kexs

Sets the allowed key exchange (KEX) methods to be offered to the server. List the KEX names in a comma-separated list. For example:

```
--kexs diffie-hellman-group14-sha256@ssh.com,diffie-hellman-group14-sha256@ssh.com
```

Enter help as the value to view the currently supported KEX methods.

All the supported KEXs can operate in the FIPS mode on Linux, Windows, Solaris and HP-UX Itanium. However, diffie-hellman-group15-sha256@ssh.com, diffie-hellman-group15-sha256@ssh.com, ecdh-sha2-nistp256, ecdh-sha2-nistp384 and ecdh-sha2-nistp521 that are supported KEXs, cannot operate in the FIPS mode on HP-UX PA-RISC and IBM AIX due to issues in the OpenSSL cryptographic library version 0.9.8.
Sets the allowed host key algorithms to be offered to the server. List the host key algorithms in a comma-separated list. For example:

```
--hostkey-algs ssh-dss-sha224@ssh.com,ssh-dss-sha256@ssh.com
```

Enter **help** as the value to view the currently supported host key algorithms.

**-n, --dev-null (Unix), -n, --null (Windows)**

Redirects input from `/dev/null` (Unix) and from NUL (Windows).

**-o option**

Processes an option as if it was read from a Tectia Client 4.x-style configuration file. The supported options are `ForwardX11`, `ForwardAgent`, `AllowedAuthentications` and `PidFile`. For example, `-o "ForwardX11=yes"`. Also `-o "PidFile=/tmp/sshg3.pid"` makes sshg3 to store its process ID into file "/tmp/sshg3.pid" if it goes into background.

**-P, --password= PASSWORD| file://PASSWORDFILE| extprog://PROGRAM**

Sets user password that the client will send as a response to password authentication. The `PASSWORD` can be given directly as an argument to this option (not recommended). Better alternatives are entering a path to a file containing the password (`--password=file://PASSWORDFILE`), or entering a path to a program or script that outputs the password (`--password=extprog://PROGRAM`).

When using the `extprog://` option to refer to a shell script, make sure the script also defines the user's shell, and outputs the actual password. Otherwise the executed program fails, because it does not know what shell to use for the shell script. For example, if the password string is defined in a file named `my_password.txt`, and you want to use the bash shell, include these lines in the script:

```bash
#!/usr/bash
cat /full/pathname/to/my_password.txt
```

**Caution**

Supplying the password on the command line is not a secure option. For example, in a multi-user environment, the password given directly on the command line is trivial to recover from the process table. You should set up a more secure way to authenticate. For non-interactive batch jobs, it is more secure to use public-key authentication without a passphrase, or host-based authentication. At a minimum, use a file or a program to supply the password.

**-p, --port=PORT**

Connects to this port on the remote host. A Secure Shell server must be listening on the same port.

**-q**

Quiet mode, reports only fatal errors. This option overrides the `quiet-mode` setting made in the Connection Broker configuration file.
-R, --remote-fwd [protocol/] [listen-address:] listen-port:dst-host:dst-port

Forwards a port on the remote (server) host to a destination host and port on the local side.

This allocates a listener port (listen-port) on the remote server. Whenever a connection is made to this listener, the connection is tunneled over Secure Shell to the local client and another connection is made from the client to a specified destination host and port (dst-host:dst-port). The connection from the client onwards will not be secure, it is a normal TCP connection.

Giving the argument protocol enables protocol-specific forwarding. The protocols implemented are tcp (default, no special processing) and ftp (temporary forwarding is created for FTP data channels, effectively securing the whole FTP session).

If listen-address is given, only that interface on the server is listened. If it is omitted, all interfaces are listened.

-S, --no-session-channel

Does not request a session channel. This can be used with port-forwarding requests if a session channel (and tty) is not needed, or the server does not give one.

+S

Requests a session channel. This is the default value.

-s, --subsystem subsystem remote_server

Sets a subsystem or a service to be invoked on the remote server. The subsystem is specified as a remote command. For example: sshg3 -s sftp <server>

-t, --tty

Allocates a tty even if a command is given.

-v, --verbose

Uses verbose mode. More information or error diagnostics are output if a connection fails.

-x, -X, --no-x11-forwarding

Disables X11 connection forwarding. This is the default value.

+x, +X

Enables X11 connection forwarding.

-z, --broker-log-file=FILE

Sets the Connection Broker log file to FILE. This option works only if ssh-broker-g3 gets started by this process).
--aa, --allowed-authentications=METHODS

Defines the only allowed methods that can be used in user authentication. List the methods in a comma-separated list. For example:

```
--allowed-authentications keyboard-interactive,password
```

Enter help as the value to view the currently supported authentication methods.

--abort-on-failing-tunnel

Aborts if creating a tunnel listener fails (for example, if the port is already reserved).

--compressions=METHODS

Sets the allowed compression methods to be offered to the server. List the methods in a comma-separated list.

Enter help as the value to view the currently supported compression methods.

--disconnect-message=MESSAGE

Sets a message that is displayed when disconnected. The message may contain any of the following substitution variables:

- **time**: Time of disconnect.
- **random**: 16 random hexadecimal digits.
- **random4**: 4 random hexadecimal digits.
- **random8**: 8 random hexadecimal digits.
- **random16**: Same as random.
- **pid**: Process id of sshg3.
- **broker_pid**: Broker process id.
- **conn_id**: Connection id.
- **session_id**: Session id.
- **target_host**: Target server name.
- **target_port**: Target server port.

If any of the random variables are used in a disconnect message, the random values are displayed to the user before the authentication-success message.

--exclusive

Defines that a new connection will be opened for each connection attempt, otherwise Connection Broker can reuse recently closed connections.
--hostkey-policy=POLICY

Defines the policy for checking server host keys and handling unknown server host keys. The possible values are:

• ask (default): The user will be asked to verify and accept the server host keys, if the keys are not found in the host key storage or if the keys have changed.

• strict: The connection to the server will be allowed only if the host key is found in the user's known host keys storage.

• tofu: Trust on first use; new host keys are stored without prompting the user to accept them.

• advisory (not recommended): New host keys are stored without prompting the user to accept them, and connections are allowed also to servers offering a changed host key.

⚠️ Caution
Consider carefully before setting the policy to advisory. Disabling the host-key checks makes the connection vulnerable to attacks.

You can also configure the host key policy in the ssh-broker-config.xml configuration file with the <auth-server-publickey> element in the default-settings and per profile. See auth-server-publickey.

If this option is set on the command-line client and configured in the ssh-broker-config.xml, the command-line value will be used.

--identity=ID

Defines that the ID of the private key is used in user authentication. The ID can be Connection Broker-internal ordinary number of the key, the key hash or the key file name.

--identity-key-hash ID

Defines the private key used in user authentication with the corresponding public key hash.

--identity-key-id ID

Defines that the Connection Broker-internal ordinary number of the key is used in user authentication.

--keep-alive=VALUE

Defines how often keep-alive messages are sent to the Secure Shell server. Enter the value as seconds. The default value is 0, meaning that keep-alive messages are disabled.

--kip

Defines keyboard-interactive and password as the allowed methods for user authentication; the same as

--allowed-authentications keyboard-interactive, password
--remote-environment name=VALUE

When this option is used, the defined environment variables are passed to the server from the client side. The environment variables are applied on the server when requesting a command, shell or subsystem.

Note that the server can restrict the setting of environment variables.

You can also configure the environment variables to be passed to the server in the ssh-broker-config.xml configuration file with the <remote-environment> element in the default-settings and per profile. See remote-environment.

If the same variable is entered on the command-line client and configured in the ssh-broker-config.xml, the command-line version will be used.

--remote-environment-format name=VALUE

The defined environment variables are passed to the server from the client side. The Connection Broker processes the value before sending it to the server.

You can use %U in the value to indicate a user name. The Connection Broker replaces the %U with the actual user name before sending it to the server.

For more information, see the --remote-environment option above.

--tcp-connect-timeout=VALUE

Defines a timeout period (in seconds) for establishing a TCP connection to the Secure Shell server. Enter the value as a positive number.

-V, --version

Displays program version and exits.

-h, --help, -?

Displays a short summary of command-line options and exits.

## Commands

sshg3 can take as a command either of the following ones:

remote_command [arguments] ...  

Runs the command on a remote host.

-s service

Enables a service in remote server.

## Escape Sequences
sshg3 supports escape sequences to manage a running session. For an escape sequence to take effect, it must be typed directly after a newline character (press Enter first). The escape sequences are not displayed on screen during typing.

The following escape sequences are supported:

~.

Terminates the connection.

~

Suspends the session.

~#

Sends the escape character literally.

~

Lists forwarded connections.

~

Disables the escape character irrevocably.

~?

Displays a summary of escape sequences.

~r

Initiates rekeying manually.

~s

Gives connection statistics, including server and client version, packets in, packets out, compression, key exchange algorithms, public-key algorithms, and symmetric ciphers.

~u

Uploads the chosen public key automatically to the server. If the user has only one key, it will be uploaded. Otherwise the largest key with a name that matches id_rsa_<size>_a will be selected.

~U

Uploads a public key to the server. A list of available keys is printed and the user is prompted to select one to be uploaded.

~c

Gives statistics for individual channels (data window sizes etc). This is for debugging purposes.
```
~V

Dumps the client version number to stderr (useful for troubleshooting).

Environment Variables

Upon connection, the Secure Shell server will automatically set a number of environment variables that
 can be used by sshg3. The exact variables set depend on the Secure Shell server. The following variables
 can be used by sshg3:

DISPLAY

The DISPLAY variable indicates the location of the X11 server. It is automatically set by the server
to point to a value of the form hostname:n where hostname indicates the host on which the server
and the shell are running, and n is an integer greater than or equal to 1. sshg3 uses this special value
to forward X11 connections over the secure channel.

The user should normally not set DISPLAY explicitly, as that will render the X11 connection unsecured
(and will require the user to manually copy any required authorization cookies).

HOME

The user's home directory.

LOGNAME

Synonym for USER; set for compatibility with systems using this variable.

MAIL

The user's mailbox.

PATH

Set to the default PATH, depending on the operating system or, on some systems, /etc/environment
or /etc/default/login.

SSH_SOCKS_SERVER

The address of the SOCKS server used by sshg3.

SSH2_AUTH_SOCK

If this exists, it is used to indicate the path of a Unix-domain socket used to communicate with the
authentication agent (or its local representative).

SSH2_CLIENT

Identifies the client end of the connection. The variable contains three space-separated values: client
IP address, client port number, and server port number.
```
**SSH2_ORIGINAL_COMMAND**

This will be the original command given to sshg3 if a forced command is run. It can be used, for example, to fetch arguments from the other end. This does not have to be a real command, it can be the name of a file, device, parameters or anything else.

**SSH2_TTY**

This is set to the name of the tty (path to the device) associated with the current shell or command. If the current session has no tty, this variable is not set.

**TZ**

The time-zone variable is set to indicate the present time zone if it was set when the server was started (the server passes the value to new connections).

**USER**

The name of the user.

For a list of variables set by Tectia Server, see the ssh-server-g3(8) man page.

**Exit Values**

sshg3 returns the following values based on the result of the operation:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Operation was successful.</td>
</tr>
<tr>
<td>1</td>
<td>sshg3 has encountered an error, the reason is usually given in an error message.</td>
</tr>
</tbody>
</table>

When executing remote commands, sshg3 exits with the status of the command run indicated with exit codes:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The remote command was run successfully.</td>
</tr>
<tr>
<td>127</td>
<td>The requested remote command was not found.</td>
</tr>
</tbody>
</table>

**Examples**

Connect as the local user name to host `remotehost`, port 2222, and open shell:

```
$ sshg3 remotehost#2222
```

Connect to the host specified by the connection profile `profile1` in the `ssh-broker-config.xml` file, and run the `who` command (and exit after running the command):

```
$ sshg3 profile1 who
```

Connect as `user` to host `remotehost`, and open a local port forwarding from port 143 on the client to port 143 on `imapserver`. Do not open shell. Also other hosts may connect to the local port. The connection from `remotehost` to `imapserver` will not be secured:

```
$ sshg3 -L 143:imapserver:143 -g -S user@remotehost
```
**scpg3**

scpg3 — Secure Shell file copy client - Generation 3

**Synopsis**

```bash
scpg3 [options...]
[ src_profile: | [user@] src_host [port]: | src_file...]
[ dst_profile: | [user@] dst_host [port]: | dst_file_or_dir]
```

**Description**

`scpg3` (scpg3.exe on Windows) is used to securely copy files over the network. `scpg3` launches `ssh-broker-g3` to provide a secure transport using the Secure Shell version 2 protocol. `ssh-broker-g3` will ask for passwords or passphrases if they are needed for authentication. `scpg3` uses the configuration specified in the `ssh-broker-config.xml` file.

Copies between two remote hosts are permitted. The remote host(s) must be running a Secure Shell version 2 server with the `sftp-server` (or `sft-server-g3`) subsystem enabled. Tectia Server has `sft-server-g3` enabled by default.

Any filename may contain a host, user, and port specification to indicate that the file is to be copied to or from that host ([user@]host[port]). If no user name is given, the local user name is assumed. If no port is given, the default Secure Shell port 22 is assumed. Alternatively, a connection profile defined in the `ssh-broker-config.xml` file (profile) can be given.

**Note**

When entering a connection profile in the `scpg3` command, note that Tectia Client deduces the meaning of the argument differently depending on its format. If there is an @ sign in the given attribute value, Tectia Client always interprets it to be <username@hostname>, i.e. not a profile.

Also, if there are dots in a profile name (for example `host.x.example.com`, the dots need to be escaped on command line. On Unix, enter `host\.x\.example\.com`, instead. On Windows, enter `host".x".example".com`, instead. Otherwise the profile name is taken as a host name and the current Windows user name is used for logging in.

The `host` parameter can optionally be enclosed in square brackets ([[]]) to allow the use of semicolons. The `file` argument can contain simple wildcards: asterisk (*) for any number of any characters, and question mark (?) for any one character.

For information on special characters in file names, see the section called “Filename Support”.

**Options**

The following command-line parameters can be used to further specify the `scpg3` options.
-4

Defines that all connection-related DNS resolutions will be resolved as an IPv4 address.

-6

Defines that all connection-related DNS resolutions will be resolved as an IPv6 address.

-a [arg]

Transfers files using the ASCII mode, that is, newlines will be converted on the fly. For transfers between Tectia on z/OS and other hosts, this also enables automatic ASCII-EBCDIC conversions. See the `sftpg3 ascii` command in the section called "Commands".

If the server does not advertise the newline convention, and you are not using a host profile that specifies its host type, you can give `scpg3` a hint by giving an argument after `-a`. The default is to set the destination newline convention, but you can specify either one by prefixing the argument with `src:` or `dest:` for source or destination convention, respectively. The available conventions are `dos`, `unix`, and `mac`, using `\r\n`, `\n`, and `\r` as newlines, respectively. Note that there is no space between the `-a` and its argument. An example is shown below:

```
$ scpg3 -asrc:unix -adest:dos src_host:src_file dest_host:dest_file
```

To force the newline conventions, use these values: `force-dos`, `force-unix`, and `force-mac`. These settings force the newline mode irrespective of what the remote SSH server suggests to the SCP client.

-B, --batch-mode

Uses batch mode. Fails authentication if it requires user interaction on the terminal.

Using batch mode requires that you have previously saved the server host key on the client and set up a non-interactive method for user authentication (for example, host-based authentication or public-key authentication without a passphrase).

-b buffer_size_bytes

Defines the maximum buffer size for one SFTP protocol read or write request (default: 32768 bytes).

The maximum number of SFTP protocol read or write requests sent in parallel within the transfer of a single file can be specified with the `-N` option.

Note that when streaming (see `--streaming`) is used (as it is by default when transferring files larger than `buffer_size_bytes` to/from Tectia Server), this option is not used for defining buffer sizes.

-C

Disables compression from the current connection.

+C

Enables zlib compression for this particular connection.
-c, --ciphers=LIST

Sets the allowed ciphers to be offered to the server. List the cipher names in a comma-separated list. For example:

```
--ciphers seed-cbc@ssh.com,aes256-cbc
```

Enter `help` as the value to view the currently supported cipher names.

-D, --debug=LEVEL

Sets the debug level. `LEVEL` is a number from 0 to 99, where 99 specifies that all debug information should be displayed. This should be the first argument on the command line.

**Note**

Option `-D` only applies on Unix. On Windows, instead of this command-line tool, use the Connection Broker debugging options `-D`, `-l`.

**Note**

The debug level can be set only when the `scpg3` command starts the Connection Broker. This option has no effect in the command if the Connection Broker is already running.

-d

Forces target to be a directory.

-I, --interactive

Prompts whether to overwrite an existing destination file (does not work with `-B`).

-i FILE

Defines that private keys defined in the identification file are used for public-key authentication.

-K, --identity-key-file=FILE

Defines that the given key file of a private key or certificate is used in user authentication. The path to the key file is given in the command.

If the file is a private key, it will be read and compared to the keys already known by the Connection Broker key store. If the key is not known, it will be decoded and added to the key store temporarily. If the file is a certificate and Connection Broker knows a matching private key, it will be used. Both the certificate and the private key can be given using multiple `-K` options on command line.

-m `fileperm`:`dirperm`

This option can be used only on Windows. Sets the default file and directory permission bits for file upload to Unix servers.
-N max_requests

Defines the maximum number of SFTP protocol read or write requests sent in parallel (default: 10).

The size of the buffer used in each read or write request can be specified with the -b option.

Note that this value applies within the transfer of a single file; it cannot be used to define the number of files sent in parallel.

When streaming (see --streaming) is used (as it is by default when transferring files larger than buffer_size_bytes specified with the -b option to/from Tectia Server), this option is not used.

-O, --offset= r<offset> | w<offset> | l<length> | t<length>

Sets offset. Offset r<offset> specifies the start offset in the source file. Offset w<offset> specifies the start offset in the destination file. Length l<length> specifies the amount of data to be copied. Truncate length t<length>, if given, specifies the length to which the destination file is truncated or expanded after the file data has been copied.

-p

Preserves the file permissions and the timestamps when both the source and the destination are on Unix file systems (including z/OS USS). Preserves the timestamps but not the file permissions, if either one, the source or the destination is on Windows. If the destination is on z/OS MVS, none will be preserved.

-P port

Connects to this Secure Shell port on the remote machine (default: 22).

-Q

Does not show progress indicator. The effect of this option is the same as using --progress-display=no.

Do not use this option together with parameter --statistics.

-q

Uses quiet mode (only fatal errors are shown). This option overrides the quiet-mode setting made in the Connection Broker configuration file.

-r

Recurses subdirectories.

-u, --unlink-source

Removes source files after copying (file move).

-v, --verbose

Uses verbose mode (equal to -D 2).
-W, --whole-file

Does not try incremental checks. By default (if this option is not given), incremental checks are tried. This option can only be used together with the --checksum option.

--aa, --allowed-authentications=METHODS

Defines the only allowed methods that can be used in user authentication. List the methods in a comma-separated list. For example:

```bash
--allowed-authentications keyboard-interactive,password
```

Enter `help` as the value to view the currently supported authentication methods.

--append

Appends data to the end of the destination file.

--binary

Uses binary transfer mode. If the server is Tectia Server for IBM z/OS, the server is requested not to perform ASCII to EBCDIC conversion, and the file is transferred using the Stream format. You can use the --src-site and --dst-site options to change the values.

--checkpoint=b <bytes>

Byte interval between checkpoint updates (default: 10 MB). This option can only be used when --checksum=checkpoint.

--checkpoint=s <seconds>

Time interval between checkpoint updates (default: 10 seconds). This option can only be used when --checksum=checkpoint.

--checksum [ =yes | no | md5 | sha1 | md5-force | sha1-force | checkpoint ]

Uses MD5 or SHA-1 checksums or a separate checkpoint database to determine the point in the file where file transfer can be resumed. Files smaller than `buffer_size_bytes` are not checked. Use `md5-force` or `sha1-force` with small files (default: yes, i.e. use SHA1 checksums in FIPS mode, MD5 checksums otherwise). Use checkpointing when transferring large files one by one.

--compressions=METHODS

Sets the allowed compression methods to be offered to the server. List the methods in a comma-separated list.

Enter `help` as the value to view the currently supported compression methods.

--dst-site=PARAM

Uses the specified site parameters with the destination files. See the `sftpg3 site` command in the section called “Commands”.
--exclusive

Defines that a new connection will be opened for each connection attempt, otherwise Connection Broker can reuse recently closed connections.

--fips

Performs the checksums using the FIPS cryptographic library.

--force-lower-case

Destination filename will be converted to lowercase characters.

--hostkey-algorithms=HOSTKEYALGORITHMS

Sets the allowed host key algorithms to be offered to the server. List the host key algorithms in a comma-separated list. For example:

```
--hostkey-algorithms ssh-dss-sha224@ssh.com,ssh-dss-sha256@ssh.com
```

Enter help as the value to view the currently supported host key algorithms.

--overwrite

Selects whether to overwrite existing destination file(s) (default: yes).

--identity=ID

Defines that the ID of the private key is used in user authentication. The ID can be Connection Broker-internal ordinary number of the key, the key hash or the key file name.

--identity-key-hash=ID

Defines the private key used in user authentication with the corresponding public key hash.

--identity-key-id=ID

Defines that the Connection Broker-internal ordinary number of the key is used in user authentication.

--keep-alive=VALUE

Defines how often keep-alive messages (non-operation packages) are sent to the Secure Shell server. Enter the value as seconds. The default value is 0, meaning that keep-alive messages are disabled.

--kexs=kexs

Sets the allowed key exchange (KEX) methods to be offered to the server. List the KEX names in a comma-separated list. For example:

```
--kexs diffie-hellman-group14-sha224@ssh.com,diffie-hellman-group14-sha256@ssh.com
```

Enter help as the value to view the currently supported KEX methods.

All the supported KEXs can operate in the FIPS mode on Linux, Windows, Solaris and HP-UX Itanium. However, diffie-hellman-group15-sha256@ssh.com.
sha384@ssh.com, ecdh-sha2-nistp256, ecdh-sha2-nistp384 and ecdh-sha2-nistp521 that are supported KEXs, cannot operate in the FIPS mode on HP-UX PA-RISC and IBM AIX due to issues in the OpenSSL cryptographic library version 0.9.8.

--kip

Defines keyboard-interactive and password as the allowed methods for user authentication; the same as

```
--allowed-authentications keyboard-interactive,password
```

--macs=LIST

Sets the allowed MACs to be offered to the server. List the MAC names in a comma-separated list. For example:

```
--macs hmac-sha1-96,hmac-md5,hmac-md5-96
```

Enter `help` as the value to view the currently supported MAC names.

--password= PASSWORD|file://PASSWORDFILE|extprog://PROGRAM

Sets user password that the client will send as a response to password authentication. The `PASSWORD` can be given directly as an argument to this option (not recommended). Better alternatives are entering a path to a file containing the password (``--password=file://PASSWORDFILE``), or entering a path to a program or script that outputs the password (``--password=extprog://PROGRAM``).

When using the `extprog://` option to refer to a shell script, make sure the script also defines the user's shell, and outputs the actual password. Otherwise the executed program fails, because it does not know what shell to use for the shell script. For example, if the password string is defined in a file named `my_password.txt`, and you want to use the bash shell, include these lines in the script:

```
#!/usr/bash
cat /full/pathname/to/my_password.txt
```

Caution

Supplying the password on the command line is not a secure option. For example, in a multi-user environment, the password given directly on the command line is trivial to recover from the process table. You should set up a more secure way to authenticate. For non-interactive batch jobs, it is more secure to use public-key authentication without a passphrase, or host-based authentication. At a minimum, use a file or a program to supply the password.

--plugin-path=PATH

Sets plugin path to `PATH`. This is only used in the FIPS mode.

--prefix=PREFIX

Adds a prefix to a filename during the file transfer. The prefix is removed after the file has been successfully transferred.
On z/OS, when applied to MVS data set names, the prefix is inserted after the High Level Qualifier (HLQ). In case you want the prefix to be a separate qualifier, include a dot at the end of the prefix:

```
--prefix=PREFIX.
```

```
--src-site=PARAM
```

Uses the specified site parameters with the source files. See the `site` command in the section called “Commands”.

```
--statistics [ -no | yes | simple ]
```

Note

In release 6.1.5, the behavior of the `--statistics` option has changed and the `--statistics-format` option has been removed. Instead of them, use the new `--summary-display` and `--summary-format` options.

The `--statistics` option chooses the style of the statistics to be shown after a file transfer operation. Note that `--statistics` and `--summary-display` must not be used together.

The `--statistics` option takes the following values:

- **no** - no statistics will be created.
- **yes** - shows a progress bar during the file transfer. This is the default. An example of the output:

  ```
  scp3 --statistics="yes" sourcefile destinationfile
  sourcefile | 127MB | 42.9MiB/s | TOC: 00:00:03 | 100%
  ```

- **simple** - simple one-line statistics will be displayed after the file transfer has ended. For example:

  ```
  scp3 --statistics=simple sourcefile destinationfile
  sourcefile | 127MB | 151.3MiB/s | TOC: 00:00:00 | 100%
  ```

```
--summary-display [ -no | yes | simple | bytes ]
```

Chooses the style of the file transfer summary data to be displayed after a file transfer operation. With the summary display, the progress bar data is also displayed by default.

Note that `--summary-display` and `--statistics` must not be used together.

The `--summary-display` option takes the following values:

- **no** - no summary data will be created. This is the default.
- **yes** - detailed summary data will be created. You can configure the contents with the `summary-format` option. By default, the following contents are displayed in the summary:

<table>
<thead>
<tr>
<th>Default settings:</th>
<th>Render for example this:</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Source: %c:%g\n&quot;</td>
<td>user@host1#22:/path/to/source/file</td>
</tr>
<tr>
<td>&quot;Source parameters: %e\n&quot;</td>
<td>X=TEXT, C=ISO8859-1,D=IBM.1047</td>
</tr>
<tr>
<td>&quot;Destination: %C:%G\n&quot;</td>
<td>user@host2#22:/path/to/destination/file</td>
</tr>
<tr>
<td>&quot;Destination parameters: %E\n&quot;</td>
<td>NONE</td>
</tr>
<tr>
<td>&quot;File size: %s bytes\n&quot;</td>
<td>123456 bytes</td>
</tr>
</tbody>
</table>
"Transferred: %t bytes\n" 123456 bytes
"Rate: %RB/s\n" 345kB/s
"Start: %xy-%xt-%xd %xh:%xm:%xs\n" 2010-01-26 13:10:56
"Stop: %Xy-%Xt-%Xd %Xh:%Xm:%Xs\n" 2010-01-26 13:23:30
"Time: %y\n" 00:12:34

simple - simple one-line summary will be displayed. For example:

scpg3 --summary-display=simple sourcefile destinationfile
sourcefile | 127MB | 151.3MiB/s | TOC: 00:00:00 | 100%

bytes - basic statistics reporting the transferred bytes will be displayed. For example:

scpg3 --summary-display=bytes sourcefile destinationfile
Transferred 12915145984 bytes, file: 'sourcefile' -> 'destinationfile'

--summary-format= FORMAT_STRING

Chooses the format and the contents of the summary. You can use this option when --summary-display=yes. Do not use this option with --statistics.

Select the contents for the summary using the following definitions:

%c  - source connection: user@host#port or profile
%C  - destination connection: user@host#port or profile
%D* - current date
%e  - source parameters (file transfer and data set parameters)
%E  - destination parameters (file transfer and data set parameters)
%f  - source file name
%F  - destination file name
%g  - /path/to/source/file
%G  - /path/to/destination/file
%k  - compression done ("zlib" or "none")
%p  - transfer percentage
%q  - transfer rate in bit/s
%Q  - transfer rate as "XXyb/s" (b/s, kib/s, MiB/s, GiB/s)
%r  - transfer rate in bytes/s
%R  - transfer rate as "XXyB/s" (B/s, kiB/s, MiB/s, GiB/s)
%s  - file size in bytes
%S  - file size as "XXyB" (B, kiB, MiB or GiB)
%t  - transfer size in bytes
%T  - transfer size as "XXyB" (B, kiB, MiB or GiB)
%x* - start date
%X* - end date
%y  - elapsed time
%Y  - time remaining
%z  - ETA or TOC, if transfer has finished
%Z  - string "ETA" or "TOC", if transfer has finished

Where * is one of the following:

h - hours (00-23)
m - minutes (00-59)
s - seconds (00-59)
f - milliseconds (0-999)
d - day of the month (1-31)
 t - month (1-12)
 y - year (1970-)

Other special characters in format strings are:
\n - line feed
\r - carriage return
\t - horizontal tab
\ - backslash

`--progress-display [no | bar | line]`

Chooses the mode of displaying the progress during a file transfer operation. The default is `bar`, which shows a progress bar. Option `line` shows the progress information according to the settings made in the `--progress-line-format` option.

Do not use this option with `--statistics`.

`--progress-line-format=FORMAT_STRING`

Chooses what information will be shown on the progress line. You can use this option when `--progress-display=line`.

Do not use this option with `--statistics`.

Select the contents for the progress line using the definitions described for command: `--summary-format`

`--progress-line-interval=seconds`

Defines how often the progress information is updated in line mode. The interval is given in seconds, and the default is 60 seconds.

Do not use this option with `--statistics`.

`--streaming [yes | no | force | ext]`

Uses streaming in file transfer, if server supports it. Files smaller than `buffer_size_bytes` are not transferred using streaming. Use `force` with small files. Default: `yes`

Use `ext` with z/OS hosts to enable direct MVS data set access. Use this option only when the file transfer is mainly used for mainframe data set transfers, as it can slow down the transfer of small files in other environments.

The `--streaming=ext` option requires also the `--checksum=no` option, because if checksums are calculated, the file transfer uses staging, which excludes streaming.

`--sunique`

Stores files with unique names. In case more than one of the transferred files have the same name, this feature adds a sequential number to the end of the repeated file name, for example: `file.name, file.name1, and file.name2`. 

© 1995–2021 SSH Communications Security Corporation

Tectia® Client 6.4 User Manual
--tcp-connect-timeout=VALUE

Defines a timeout period (in seconds) for establishing a TCP connection to the Secure Shell server. Enter the timeout value as a positive number. Value 0 (zero) disables this feature and the default system TCP timeout will be used, instead.

--user=USERNAME

Logs in using this user name if the user name is not provided in the address string.

-V, --version

Displays program version and exits.

-h, --help, -?

Displays a short summary of command-line options and exits.

Filename Support

Different operating systems allow different character sets in filenames. On Unix, some of the special characters are allowed in filenames, but on Windows, the following characters are not allowed:

\ / : * ? " < > |

When you use the scpg3 command to copy files with special characters (for example unixfilename*?".txt) from a Unix server to Windows, you need to provide the files with new names that are acceptable on Windows. Enter the commands in the following format:

$ scpg3 user@unixserver:"unixfilename*?".txt" windowsfilename.txt

The general rule is to follow your platform specific syntax when you enter filenames containing special characters as arguments to the scpg3 command.

Tectia fully supports filenames containing only ASCII characters. Filenames containing characters from other character sets are not guaranteed to work.

Using Wildcards

The scpg3 command supports * and ? as wildcards.

The wildcards can be used both on the remote and the local side in the commands. The following example command will copy all text files (*.txt) from all subdirectories of directory dir2 whose names begin with the prefix data- into the current local directory (.):

$ scpg3 -r user@server:"dir2/data-*/*.txt" .

Note that on Unix, the characters * and ? can appear also in the filenames. So it is necessary to use escape characters to distinguish the wildcards from the characters belonging to a filename. See more information in the section called “Escaping Special Characters”.

Tectia® Client 6.4 User Manual

© 1995–2021 SSH Communications Security Corporation
Escaping Special Characters

Some special characters that are used in filenames in different operating systems, may have a special meaning in the Tectia commands. Note also that the meaning can be different in various parts of the file transfer system.

In the `scpg3` command, the following characters have a special meaning, and they need to be escaped in commands that take filenames as arguments:

* asterisk is a wildcard for any number of any characters

? question mark is a wildcard for any single character

""" quotation marks placed around strings that are to be taken 'as is'

\ backslash is an escape character on Unix

~ tilde is an escape character on Windows.

The escape character tells the `scpg3` command to treat the next character "as is" and not to assume any special meaning for it. The escape character is selected according to the operating system of the local machine.

Note that the \ and ~ characters are special characters themselves, and if they are present in the filename, escape characters must be placed in front of them, too. Therefore, if you need to enter a filename containing \ in Unix or ~ in Windows to the `scpg3` command, add the relevant escape character to it:

\ on Unix

~~ on Windows

See the examples below to learn how the escape characters are used in the Tectia `scpg3` command, and how to enter filenames with special characters in different operating systems.

Examples of filenames in the `scpg3` command:

The following filenames are valid in Unix, but they need escape characters in the commands:

```
file|name.txt
file="name".txt
file?name.txt
file*name.txt
file\name.txt
file - name.txt
file-name.txt
```

When using the `scpg3` command on Unix, in certain cases several escape characters are needed, as they escape one another. Enter the above mentioned filenames in the following formats:

```
file\|name.txt  or  "file\|name.txt"
file-"name".txt
file\\?name.txt  or  "file\?name.txt"
```
Example commands on Unix:

```
$ scp g3 user@server: file\*name.txt .
$ scp g3 user@server: file - name.txt .
```

When using the `scpg3` command on Windows, enter the above mentioned Unix filenames in the following formats:

```
"file\*\name.txt"
file-"\name.txt" (Note that Windows requires \ to escape the " character)
"file~*\name.txt"
"file~\name.txt"
file-\name.txt
"file -\name.txt"
file~~\name.txt
```

The operating system interprets the quotation marks (""") here so that the `scpg3` command receives the string without the quotation marks as a parameter.

Example commands on Windows:

```
> scpg3 user@server:"file~*\name.txt" filename.txt
> scpg3 user@server:"file -\name.txt" .
```

**Environment Variables**

`scpg3` uses the following environment variables:

`SSH_SFTP_CHECKSUM_MODE` = yes|no|md5|sha1|md5-force|sha1-force|checkpoint

Defines the setting for comparing checksums. For more information on the available values, see `checksum`.

`SSH_SFTP_SHOW_BYTE_COUNT` = yes|no

If this variable is set to yes, the number of transferred bytes is shown after successful file transfer. Also the names of source and destination files are shown. The default is no.

`SSH_SFTP_STATISTICS` = yes|no|simple

If this variable is set to yes (default), normal progress bar is shown while transferring the file. If it is set to no, progress bar is not shown. If it is set to simple file transfer statistics are shown after the file has been transferred.

**Exit Values**
scpg3 returns the following values based on the result of the operation:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Operation was successful.</td>
</tr>
<tr>
<td>1</td>
<td>Internal error.</td>
</tr>
<tr>
<td>2</td>
<td>Connection aborted by the user.</td>
</tr>
<tr>
<td>3</td>
<td>Destination is not a directory, but a directory was specified by the user.</td>
</tr>
<tr>
<td>4</td>
<td>Connecting to the host failed.</td>
</tr>
<tr>
<td>5</td>
<td>Connection lost.</td>
</tr>
<tr>
<td>6</td>
<td>File does not exist.</td>
</tr>
<tr>
<td>7</td>
<td>No permission to access file.</td>
</tr>
<tr>
<td>8</td>
<td>Undetermined error from sshfilexfer.</td>
</tr>
<tr>
<td>11</td>
<td>Some non-fatal errors occurred during a directory operation.</td>
</tr>
<tr>
<td>101</td>
<td>Wrong command-line arguments specified by the user.</td>
</tr>
</tbody>
</table>

**Examples**

Copy files from your local system to a remote Unix system:

$ scpg3 localfile user@remotehost:/dst/dir/

Copy files from your local system to a remote Windows system:

$ scpg3 localfile user@remotehost:/C:/dst/dir/

Copy files from a remote system to your local disk:

$ scpg3 user@remotehost:/src/dir/srcfile /dst/dir/dstfile

Copy files from one remote system to another using connection profiles defined in the `ssh-broker-config.xml` file:

$ scpg3 profile1:/src/dir/srcfile profile2:/dst/dir/dstfile
sftpg3

sftpg3 — Secure Shell file transfer client - Generation 3

Synopsis

sftpg3 [options...]
[profile | user@host [#port]]

Description

sftpg3 (sftpg3.exe on Windows) is an FTP-like client that can be used for secure file transfer over the network. sftpg3 launches ssh-broker-g3 to provide a secure transport using the Secure Shell version 2 protocol. ssh-broker-g3 will ask for passwords or passphrases if they are needed for authentication. sftpg3 uses the configuration specified in the ssh-broker-config.xml file.

When started interactively, sftpg3 displays a prompt where the SFTP commands can be entered. It is also possible to start sftpg3 non-interactively with a batch file that contains the commands to be run. For information on the available commands, see the section called “Commands”.

As an alternative to using the command line to set default values for various parameters, it is possible to define the commands in a startup batch file that is run each time sftpg3 is started. By default, sftpg3 looks for a file named ssh_sftp_batch_file in the user-specific directory $HOME/.ssh2/ on Unix or %APPDATA%\SSH\ on Windows.

sftpg3 has two connection end points, local and remote, and both of them can be connected to other hosts than the SFTP client host. If started without arguments, the local end point is connected to the file system of the SFTP client host and the remote end point is unconnected. The connected host(s), with the exception of the SFTP client host, must be running a Secure Shell version 2 server with the sftp-server (or sft-server-g3) subsystem enabled. Tectia Server has sft-server-g3 enabled by default.

The remote connection end point can be given directly as an argument to the sftpg3 command or it can be given with the open SFTP command after sftpg3 has started. The local connection end point can be given with the open SFTP command.

When connecting, you can give either the name of a connection profile defined in the ssh-broker-config.xml file (profile) or the IP address or DNS name of the remote host, optionally with the remote user name and the port of the Secure Shell server ([user@host [#port]]). If no user name is given, the local user name is assumed. If no port is given, the default Secure Shell port 22 is assumed.

Note

When entering a connection profile in sftpg3, note that Tectia Client deduces the meaning of the argument differently depending on its format. If there is an @ sign in the given attribute value, Tectia Client always interprets it to be <username@hostname>, i.e. not a profile.
Also, if there are dots in a profile name (for example host.x.example.com, the dots need to be escaped on command line. On Unix, enter host\.x\.example\.com, instead. On Windows, enter host˜.x˜.example˜.com, instead. Otherwise the profile name is taken as a host name and the current local user name is used for logging in.

For information on special characters in filenames, see the section called “Filename Support”.

**Options**

The following options are available:

- `–4`

  Defines that all connection-related DNS resolutions will be resolved as an IPv4 address.

- `–6`

  Defines that all connection-related DNS resolutions will be resolved as an IPv6 address.

- `–b buffer_size_bytes`

  Defines the maximum buffer size for one SFTP protocol read or write request (default: 32768 bytes).

  The maximum number of SFTP protocol read or write requests sent in parallel within the transfer of a single file can be specified with the `-N` option.

  Note that when streaming (see `--streaming`) is used (as it is by default when transferring files larger than `buffer_size_bytes` to/from Tectia Server), this option is not used for defining buffer sizes.

- `–B [ - | batch_file ]`

  The `-B` option enables reading from the standard input. This option is useful when you want to launch processes with `sftpg3` and redirect the stdin pipes.

  By defining the name of a `batch_file` as an attribute, you can execute SFTP commands from the given file in batch mode. The file can contain any allowed SFTP commands. For a description of the commands, see the section called “Commands”.

  Using batch mode requires that you have previously saved the server host key on the client and set up a non-interactive method for user authentication (for example, host-based authentication or public-key authentication without a passphrase).

- `–C`

  Disables compression from the current connection.

- `+C`

  Enables zlib compression for this particular connection.
-c, --ciphers=LIST

Sets the allowed ciphers to be offered to the server. List the cipher names in a comma-separated list. For example:

```
--ciphers seed-cbc@ssh.com,aes256-cbc
```

Enter `help` as the value to view the currently supported cipher names.

-D, --debug=LEVEL

Sets the debug level. LEVEL is a number from 0 to 99, where 99 specifies that all debug information should be displayed. This should be the first argument on the command line.

**Note**

Option `-D` only applies on Unix. On Windows, instead of this command-line tool, use the Connection Broker debugging options `-D`, `-l`.

**Note**

The debug level can be set only when the `sftpg3` command starts the Connection Broker. This option has no effect in the command if the Connection Broker is already running.

-i FILE

Defines that private keys defined in the identification file are used for public-key authentication.

-K, --identity-key-file=FILE

Defines that the given key file of a private key or certificate is used in user authentication. The path to the key file is given in the command.

If the file is a private key, it will be read and compared to the keys already known by the Connection Broker key store. If the key is not known, it will be decoded and added to the key store temporarily. If the file is a certificate and Connection Broker knows a matching private key, it will be used. Both the certificate and the private key can be given using multiple `-K` options on command line.

-N max_requests

Defines the maximum number of SFTP protocol read or write requests sent in parallel (default: 10).

The size of the buffer used in each read or write request can be specified with the `-b` option.

Note that this value applies within the transfer of a single file; it cannot be used to define the number of files sent in parallel.

When streaming (see `--streaming`) is used (as it is by default when transferring files larger than `buffer_size_bytes` specified with the `-b` option to/from Tectia Server), this option is not used.

-P port

Connects to this Secure Shell port on the remote machine (default: 22).
-q, --quiet

Suppresses the printing of error, warning, and informational messages. This option overrides the quiet-mode setting made in the Connection Broker configuration file.

-v, --verbose

Uses verbose mode (equal to -D 2).

--aa, --allowed-authentications=METHODS

Defines the only allowed methods that can be used in user authentication. List the methods in a comma-separated list. For example:

```
--allowed-authentications keyboard-interactive,password
```

Enter help as the value to view the currently supported authentication methods.

--compressions=METHODS

Sets the allowed compression methods to be offered to the server. List the methods in a comma-separated list.

Enter help as the value to view the currently supported compression methods.

--exclusive

Defines that a new connection will be opened for each connection attempt, otherwise Connection Broker can reuse recently closed connections.

--fips

Performs the checksums using the FIPS cryptographic library.

--hostkey-algorithms=algorithms

Sets the allowed host key algorithms to be offered to the server. List the host key algorithms in a comma-separated list. For example:

```
--hostkey-algorithms ssh-dss-sha224@ssh.com,ssh-dss-sha256@ssh.com
```

Enter help as the value to view the currently supported host key algorithms.

--identity=ID

Defines that the ID of the private key is used in user authentication. The ID can be Connection Broker-internal ordinary number of the key, the key hash or the key file name.

--identity-key-hash=ID

Defines the private key used in user authentication with the corresponding public key hash.

--identity-key-id=ID

Defines that the Connection Broker-internal ordinary number of the key is used in user authentication.
--keep-alive=VALUE

Defines how often keep-alive messages are sent to the Secure Shell server. Enter the value as seconds. The default value is 0, meaning that keep-alive messages are disabled.

--kexs=kexs

Sets the allowed key exchange (KEX) methods to be offered to the server. List the KEX names in a comma-separated list. For example:

```
--kexs diffie-hellman-group14-sha224@ssh.com,diffie-hellman-group14-sha256@ssh.com
```

Enter help as the value to view the currently supported KEX methods.

All the supported KEXs can operate in the FIPS mode on Linux, Windows, Solaris and HP-UX Itanium. However, diffie-hellman-group15-sha256@ssh.com, diffie-hellman-group15-sha384@ssh.com, ecdh-sha2-nistp256, ecdh-sha2-nistp384 and ecdh-sha2-nistp521 that are supported KEXs, cannot operate in the FIPS mode on HP-UX PA-RISC and IBM AIX due to issues in the OpenSSL cryptographic library version 0.9.8.

--kip

Defines keyboard-interactive and password as the allowed methods for user authentication; the same as

```
--allowed-authentications keyboard-interactive,password
```

--macs=LIST

Sets the allowed MACs to be offered to the server. List the MAC names in a comma-separated list. For example:

```
--macs hmac-sha1-96,hmac-md5,hmac-md5-96
```

Enter help as the value to view the currently supported MAC names.

--password= PASSWORD | file://PASSWORDFILE | extprog://PROGRAM

Sets the user password or passphrase that the client will send as a response to an authentication method requesting a password or passphrase (hereafter: password). This can be used also with password-protected certificates and public-keys.

The PASSWORD can be given directly as an argument to this option (not recommended). Better alternatives are entering a path to a file containing the password (--password=file:// PASSWORDFILE), or entering a path to a program or script that outputs the password (--password=extprog://PROGRAM).

When using the extprog:// option to refer to a shell script, make sure the script also defines the user's shell, and outputs the actual password. Otherwise the executed program fails, because it does not know what shell to use for the shell script. For example, if the password string is defined in a file named my_password.txt, and you want to use the bash shell, include these lines in the script:
Caution

Supplying the password on the command line is not a secure option. For example, in a multi-user environment, the password given directly on the command line is trivial to recover from the process table. You should set up a more secure way to authenticate. For non-interactive batch jobs, it is more secure to use public-key authentication without a passphrase, or host-based authentication. At a minimum, use a file or a program to supply the password.

--plugin-path=PATH

Sets plugin path to PATH. This is only used in the FIPS mode.

--tcp-connect-timeout=VALUE

Defines a timeout period (in seconds) for establishing a TCP connection to the Secure Shell server. Enter a timeout value as a positive number. Value 0 (zero) disables this feature and the default system TCP timeout will be used, instead.

--user=USERNAME

USERNAME will be used in the logon if the user name is not specified in the address string.

-V, --version

Displays program version and exits.

-h, --help, -?

Displays a short summary of command-line options and exits.

Commands

When sftp3 is ready to accept commands, it will display the prompt sftp>. The user can then enter any of the following commands:

! append ascii auto binary
break cd chmod close continue
debug delete digest echo exit
get getext help helpall lappend
lcd lchmod lclose ldelete ldigest
lls llroots lmkdir localopen locsite
lopen lpwd lreadlink lrename lrm
lrmdir ls lsite lsroots lsymlink
mget mkdir mput open pause
put pwd quit readlink rename
rm rmdir set setext setperm
invokes an interactive shell on the local machine. if a command is given, it is used as the command to be executed. Optional arguments can be given depending on the command.

Appends the specified local file to the remote file. No globbing can be used.

Options:

- u, --unlink-source

Removes the source file after file transfer.

--streaming [yes | no | force | ext]

Uses streaming in file transfer if the server supports it. Files smaller than buffer size bytes are not transferred using streaming. Use force with small files. Default: yes

Use ext with z/OS hosts to enable direct MVS data set access. Use this option only when the file transfer is mainly used for mainframe data set transfers, as it can slow down the transfer of small files in other environments.

The --streaming=ext option requires also the --checksum=no option, because if checksums are calculated, the file transfer uses staging, which excludes streaming.

--force-lower-case

Destination filename will be converted to lowercase characters.

The semantics of options --statistics, --summary-display, --summary-format, --progress-display, --progress-line-format, and --progress-line-interval are the same as with get.

ascii [-s] [remote_nl_conv] [local_nl_conv]

Command ascii sets the transfer mode to ASCII.

For transfers between Tectia on z/OS and other hosts, this also enables automatic ASCII-EBCDIC conversion. Default conversion is between code sets ISO8859-1 and IBM-1047. Files are transferred using the LINE format. The site and lsite commands can be used to change the values.

If you enter the ascii command with any options, it does not set the transfer mode to ASCII, but affects the newline conventions used in the transferred files. You can also set the server's newline convention by using a host profile that specifies the host type. For more information, see the host-type attribute in the section called “The profiles Element”.

323
Options:

-s

Shows the current newline convention. The line delimiters used in different systems are:

<table>
<thead>
<tr>
<th>System</th>
<th>Delimiter</th>
</tr>
</thead>
<tbody>
<tr>
<td>dos</td>
<td><code>CRLF (\r\n, 0x0d 0x0a)</code></td>
</tr>
<tr>
<td>mac</td>
<td><code>CR (\r, 0x0d)</code></td>
</tr>
<tr>
<td>mvs</td>
<td><code>NEL (\n, 0x15)</code></td>
</tr>
<tr>
<td>unix</td>
<td><code>LF (\n, 0x0a)</code></td>
</tr>
</tbody>
</table>

remote_nl_conv local_nl_conv

This syntax can be used to define the remote and local newline conventions. The `local_nl_conv` option operates on the local end, but notice that usually the correct local newline convention is already compiled in.

You can either set hints of the newline conventions for the underlying transfer layer, which by default tries to use the actual newline convention given by the server, or alternatively you can force the newline mode.

To set hints of the newline conventions, use these values in the `remote_nl_conv` and `local_nl_conv` options: `dos`, `unix`, and `mac`. These settings will be used if the remote SSH server does not automatically provide any newline information to the SFTP client. For example:

```
sftp> ascii
File transfer mode is now ascii.
sftp> ascii unix dos
Newline conventions updated.
```

To force the newline conventions, use these values: `force-dos`, `force-unix`, and `force-mac`. These settings force the newline mode irrespective of what the remote SSH server suggests to the SFTP client.

```
sftp> ascii
File transfer mode is now ascii.
sftp> ascii force-unix force-dos
Newline conventions updated.
```

You can also set either one of the options to `ask`, which will cause `sftpg3` to prompt you for the newline convention when needed.

 auto

File transfer mode will be selected automatically from the file extension.

binary

Files will be transferred in binary mode.

break

Interrupts batch file execution. Batch file execution can be continued with the `continue` command.
bye

Quits the application.

cd directory

Changes the current remote working directory.

chmod [-R] [-f] [-v] OCTAL-MODE [file...]

With Unix files, sets file permissions of the specified file or files to the bit pattern OCTAL-MODE or changes the file permissions according to the symbolic mode [ugoa][+-=][rwxs].

Options:

- R

Recursively changes files and directories.

- f

Uses silent mode (error messages are suppressed).

- v

Uses verbose mode (lists every file processed).

close

Closes the remote connection.

continue

Continues interrupted batch file execution.

debug [ disable | no | debuglevel ]

Disables or enables debug. With disable or no, debugging is disabled. Otherwise, sets debuglevel as debug level string, as per command-line option -D.

delete [-H, --hash][-o, --offset][-l, --length] file

Tries to delete a file or directory specified in file. The options are the same as for rm.

digest [-H, --hash][-o, --offset][-l, --length] file

Calculates MD5 or SHA-1 digest over file data. The digest is calculated over the data on the disk. If any code or line delimiter conversion attributes are in effect, they are ignored when calculating the digest.
Options:

-\-H, --hash= [md5 | sha1 ]

Use md5 or sha1 hash algorithm (default: md5).

-\-o, --offset=OFFSET

Start reading from file offset OFFSET.

-\-l, --length=LENGTH

Read LENGTH bytes of file data.

echo Text to be echoed.

Echo the text. This command can be used for example in batch mode to print text into batch logs.

exit

Quits the application.

[--progress-line-interval] [--max-depth] file...

Transfers the specified files from the remote end to the local end. By default, directories are recursively copied with their contents, but this is configurable in the Connection Broker configuration with the SFTP compatibility mode setting (sftpg3-mode in ssh-broker-config.xml). To view the currently set SFTP compatibility mode, run command:

```bash
sftp> help get
```

The currently set compatibility mode is shown in the beginning of the help for command get.

The SFTP compatibility mode options are:

tectia

The sftpg3 client transfers files recursively from the current directory and all its subdirectories.

ftp

The get command is executed as sget meaning that it transfers a single file, and no subdirectories are copied.

openssh

Only regular files and symbolic links from the specified directory are copied, and no subdirectories are copied. Otherwise the semantics of the get command are unchanged.

Options:
-p, --preserve-attributes

Preserves the file permissions and the timestamps when both the source and the destination are on Unix file systems (including z/OS USS). Preserves the timestamps but not the file permissions, if either one, the source or the destination is on Windows. If the destination is on z/OS MVS, none will be preserved.

-u, --unlink-source

Removes the source file after file transfer. Also directories are removed, if they become empty (move mode).

-l, --interactive

Prompts whether to overwrite an existing destination file (does not work with batch mode).

--overwrite [yes|no]

Decides whether to overwrite existing destination file(s) (default: yes).

--checksum [yes|no|md5|sha1|md5-force|sha1-force|checkpoint]

Uses MD5 or SHA-1 checksums or a separate checkpoint database to determine the point in the file where file transfer can be resumed. Files smaller than buffer_size_bytes are not checked. Use md5-force or sha1-force with small files (default: yes, i.e. use MD5 checksums). Use checkpointing when transferring large files one by one.

-W, --whole-file

Does not try incremental checks. By default (if this option is not given), incremental checks are tried. This option can only be used together with the --checksum option.

--checkpoint=s<seconds>

Time interval between checkpoint updates (default: 10 seconds). This option can only be used when --checksum=checkpoint.

--checkpoint=b<bytes>

Byte interval between checkpoint updates (default: 10 MB). This option can only be used when --checksum=checkpoint.

--streaming [yes|no|force|ext]

Uses streaming in file transfer if the server supports it. Files smaller than buffer_size_bytes are not transferred using streaming. Use force with small files. Default: yes

Use ext with z/OS hosts to enable direct MVS data set access. Use this option only when the file transfer is mainly used for mainframe data set transfers, as it can slow down the transfer of small files in other environments.
The \texttt{--streaming=ext} option requires also the \texttt{--checksum=no} option, because if checksums are calculated, the file transfer uses staging, which excludes streaming.

An alternative way to activate extended streaming is to define \texttt{SSH_SFTP_STREAMING_MODE=ext} and \texttt{SSH_SFTP_CHECKSUM_MODE=no} as environment variables.

\texttt{--force-lower-case}

Destination file name will be converted to lower case characters.

\texttt{--max-depth=VALUE}

Defines whether directories are copied recursively. The value can be:

0 - unlimited recursion, directories are recursively copied with their contents

1 - copies files from the specified directory only, not from subdirectories

2-\textit{n} - copies files recursively from the specified number of directory levels. Here \textit{n} means the system-specific maximum.

This command line option overrides the recursion depth set in the Connection Broker configuration with element \texttt{sftpg3-mode} and/or the setting made using environment variable \texttt{SSH_SFTP_CMD_GETPUT_MODE}.

\texttt{--prefix=PREFIX}

Adds prefix \texttt{PREFIX} to filename during the file transfer. The prefix is removed after the file has been successfully transferred.

On z/OS, when applied to MVS data set names, the prefix will be inserted after the High Level Qualifier (HLQ) by default. In case you want the prefix to be a separate qualifier, include a dot at the end of the prefix:

\texttt{--prefix=PREFIX.}

\texttt{--statistics [\textit{no} | \textit{yes} | \textit{simple}]}

\textbf{Note}

In release 6.1.5, the behavior of the \texttt{--statistics} option has changed and the \texttt{--statistics-format} option has been removed. Instead of them, use the new \texttt{--summary-display} and \texttt{--summary-format} options.

The \texttt{--statistics} option chooses the style of the statistics to be shown after a file transfer operation. Note that \texttt{--statistics} and \texttt{--summary-display} must not be used together.

The \texttt{--statistics} option takes the following values:

\texttt{no} - no statistics will be created.

\texttt{yes} - shows a progress bar during the file transfer. This is the default. An example of the output:
sftp> get --statistics="yes" sourcefile
sourcefile | 127MB | 42.9MiB/s | TOC: 00:00:03 | 100%

simple - simple one-line statistics will be displayed after the file transfer has ended. For example:

sftp> get --statistics=simple testfile
sourcefile | 127MB | 151.3MiB/s | TOC: 00:00:00 | 100%

--summary-display [-no | yes | simple | bytes]

Chooses the style of the file transfer summary data to be displayed after a file transfer operation. With the summary display, the progress bar data is also displayed by default.

Note that --summary-display and --statistics must not be used together.

The --summary-display option takes the following values:

no - no summary data will be created. This is the default.

yes - detailed summary data will be created. You can configure the contents with the summary-format option. By default, the following contents are displayed in the summary:

Default settings:
"Source: %c:%g\n" user@host1#22:/path/to/source/file
"Source parameters: %e\n" X=TEXT, C=ISO8859-1,D=IBM.1047
"Destination: %C:%G\n" user@host2#22:/path/to/destination/file
"Destination parameters: %E\n" NONE
"File size: %s bytes\n" 123456 bytes
"Transferred: %t bytes\n" 123456 bytes
"Rate: %RB/s\n" 345kiB/s
"Start: %xy-%xt-%xd %xh:%xm:%xs\n" 2010-01-26 13:10:56
"Stop: %Xy-%Xt-%Xd %Xh:%Xm:%Xs\n" 2010-01-26 13:23:30
"Time: %y\n" 00:12:34

simple - simple one-line summary will be displayed. For example:

sftp> get --summary-display=simple sourcefile
sourcefile | 127MB | 151.3MiB/s | TOC: 00:00:00 | 100%

bytes - basic statistics reporting the transferred bytes will be displayed. For example:

sftp> get --summary-display=bytes sourcefile
Transferred 12915145984 bytes, file: 'sourcefile' -> 'destinationfile'

--summary-format=FORMAT_STRING

Chooses the format and the contents of the summary. You can use this option when --summary-display=yes. Do not use this option with --statistics.

Select the contents for the summary using the following definitions:

%c - source connection: user@host#port or profile
%C - destination connection: user@host#port or profile
%D* - current date
%e - source parameters (file transfer and data set parameters)
Appendix C Command-Line Tools and Man Pages

%e  - destination parameters (file transfer and data set parameters)
%f  - source file name
%f  - destination file name
%g  - /path/to/source/file
%G  - /path/to/destination/file
%k  - compression done ("zlib" or "none")
%p  - transfer percentage
%q  - transfer rate in bit/s
%Q  - transfer rate as "XXyb/s" (b/s, kib/s, MiB/s, GiB/s)
%r  - transfer rate in bytes/s
%R  - transfer rate as "XXyB/s" (B/s, KiB/s, MiB/s, GiB/s)
%s  - file size in bytes
%S  - file size as "XXyB" (B, KiB, MiB or GiB)
%t  - transfer size in bytes
%T  - transfer size as "XXyB" (B, KiB, MiB or GiB)
%x* - start date
%X* - end date
%y  - elapsed time
%Y  - time remaining
%z  - ETA or TOC, if transfer has finished
%Z  - string "ETA" or "TOC", if transfer has finished

Where * is one of the following:

h - hours (00-23)
m - minutes (00-59)
s - seconds (00-59)
f - milliseconds (0-999)
d - day of the month (1-31)
t - month (1-12)
y - year (1970-)

Other special characters in format strings are:

\n - line feed
\r - carriage return
\t - horizontal tab
\\ - backslash

--progress-display [ -no | bar | line ]

Chooses the mode of displaying the progress during a file transfer operation. The default is bar, which shows a progress bar. Option line shows the progress information according to the settings made in the --progress-line-format option.

Do not use this option with --statistics.

--progress-line-format=FORMAT_STRING

Chooses what information will be shown on the progress line. You can use this option when --progress-display=line.

Do not use this option with --statistics.
Select the contents for the progress line using the definitions described for option `--summary-format` of the `get` command above.

`--progress-line-interval=seconds`

Defines how often the progress information is updated in the line mode. The interval is given in seconds, and the default is 60 seconds.

Do not use this option with `--statistics`.

`getext`

Displays the extensions that will be ASCII in the auto transfer mode.

`lappend [options...] srcfile [dstfile]`

The same as `append`, but appends the specified remote file to the local file.

`lcd directory`

Changes the current local working directory.

`lchmod [-R][-f][-v] OCTAL-MODE [file...]`

The same as `chmod`, but operates on local files.

`lclose`

Closes the local connection.

`ldelete [options...] file...`

The same as `delete`, but operates on local files.

`ldigest [-H, --hash][-o, --offset][-l, --length] file`

The same as `digest`, but operates on local files.

`lls [-R][-l][-S][-r][-p][-z|+z][file...]`

The same as `ls`, but operates on local files.

`llsroots`

The same as `lsroots`, but operates on local files (when the local end has been opened to a VShell server).

`lmkdir directory`

The same as `mkdir`, but operates on local files.
localopen \[user@hostname[#port][-l][-user=USERNAME]\]

The same as lopen.

lopen \[user@hostname[#port][-l][-user=USERNAME]\]

Tries to connect the local end to the host hostname. If this is successful, lls and friends will operate on the file system on that host.

Options:

- \(-l\)

  Connects the local end to the file system of the SFTP client host (which does not require a server). This is also the default state when no lopen commands have been given.

- \(--user=USERNAME\)

  Defines the user in the connection to be USERNAME.

locsite \[none|name1=value1 name2=value2...\]

The same as site, but operates on local files and data sets.

lpwd

  Prints the name of the current local working directory.

lreadlink path

  The same as readlink, but operates on local files.

lrename oldfile newfile

  The same as rename, but operates on local files.

lrm [options...] file...

  The same as rm, but operates on local files.

lrmdir directory

  The same as rmdir, but operates on local files.

ls [-R] [-l] [-S] [-r] [-p] [-z|+z] [file...]

  Lists the names of files on the remote server. For directories, contents are listed. If no arguments are given, the contents of the current working directory are listed.

  Options:

  - \(-R\)

    Directory trees are listed recursively. By default, subdirectories of the arguments are not visited.
-l

Permissions, owners, sizes and modification times are also shown (long format).

-S

Sorting is done based on file sizes (default: alphabetical sorting).

-r

The sort order is reversed.

-p

Only one page of listing is shown at a time.

-z

The client generates the long output.

+z

The long output supplied by the server is used, if available (alias for option -l).

lsite\[ none | name1=value1 name2=value2... \]

The same as site, but operates on local files and data sets.

lsroots

Dumps the virtual roots of the server. (This is a VShell extension. Without this you cannot know the file system structure of a VShell server.)

lsymlink targetpath linkpath

The same as symlink, but operates on local files.

mget options... file...

Synonymous to get.

mkdir directory

Tries to create the directory specified in directory.

mput options... file...

Transfers the specified files from the local end to the remote end. Options and semantics are the same as for get. Synonymous to put.

open [user@]hostname [#port] [-1] [--user=USERNAME]

Tries to connect the remote end to the host hostname.
Options:

-l

Connects the remote end to the file system of the SFTP client host (which does not require a server).

--user

Defines the user in the connection to be USERNAME.

pause [seconds]

Pauses batch file execution for seconds seconds, or if seconds is not given until ENTER is pressed.

put [options...] file...

Transfers the specified files from the local end to the remote end. Options and semantics are the same as for get.

pwd

Prints the name of the current remote working directory.

quit

Quits the application.

readlink path

Provided that path is a symbolic link, shows where the link is pointing to.

rename oldfile newfile

Tries to rename the oldfile to newfile. If newfile already exists, the files are left intact.

rm [-I, --interactive] [-r, --recursive] file...

Tries to delete a file or directory specified in file.

Options:

-I, --interactive

Prompts whether to remove a file or directory (does not work with batch mode).

-r, --recursive

Directories are removed recursively.

rmdir directory

Tries to delete the directory specified in directory. This command removes the directory only if it is empty and has no subdirectories.
set [ defaults | [ --commands=name1,name2,... exit-value=VALUE ] | option1=value1
    option2=value2... ]

Sets the default values for various parameters. The set command takes the following options:

**defaults**

Sets the parameters to be system defaults.

**checksum [ =yes | no | md5 | sha1 | md5-force | sha1-force | checkpoint ]**

Uses MD5 or SHA-1 checksums or a separate checkpoint database to determine the point in the file where file transfer can be resumed. Files smaller than `buffer_size_bytes` are not checked. Use `md5-force` or `sha1-force` with small files. The default is `md5` (in z/OS the default is `no`). Use checkpointing when transferring large files one by one.

**compatibility-mode [ =tectia | ftp | openssh ]**

Defines what mode of recursiveness is used in the file transfer:

**tectia**

The `sftpg3` client transfers files recursively from the current directory and all its subdirectories. This is the default mode.

**ftp**

A single file is transferred, and no subdirectories are copied.

**openssh**

Only regular files and symbolic links from the specified directory are copied, and no subdirectories are copied.

**compressions [ =none | zlib ]**

Defines whether compression is used in file transfer:

**none**

Compression is not used. This is the default.

**zlib**

Enables zlib compression in file transfer.

**exit-value=VALUE**

Defines the exit value of `sftpg3` in batch mode in case of an error. The value must be between 0 and 255. If `exit-value` is set to something else than 0 and the `--commands` parameter is not used, batch execution terminates when the first error occurs.
Example 1: If the rename command in this batch job fails, `sftpg3` will stop and return exit value "6":

```
open user@host
set exit-value=6
rename file file2
<next command in batch job>
quit
```

Example 2: If you want to ignore a possible failure of a specific command and return exit value "0" independent of the actual result of the operation, use `set exit-value=0` after the command. This example batch job ignores possible failure in renaming a file:

```
open user@host
rename file file2
set exit-value=0
<next command in batch job>
quit
```

```
--commands=namel,name2,... exit-value=VALUE
```

This option makes an `sftpg3` batch job abort when any of the specified commands fail. When a command that is not specified with this option fails, the batch job execution continues, and the exit value of the batch job is set to the one defined with `exit-value`. Note that if `exit-value=0`, the exit value of the failed command will be returned.

Example 3: When `sftpg3` is running in batch mode, it will abort execution if a `put`, `get`, or `ls` command fails. If any other command (with the exceptions mentioned below) fails, execution will continue until the end of the batch file. In both cases value "3" will be returned:

```
set --commands=put,get,ls exit-value=3
```

Example 4: When `sftpg3` is running in batch mode, it will abort execution when a `put` or `get` command fails. If any other command (with the exceptions mentioned below) fails, execution will continue. In any case the original exit value of the last failed command will be returned:

```
set --commands=put,get exit-value=0
```

Exceptions: When `exit-value` is set for specific commands with the `--commands` option, also the following situations will cause the batch job execution to abort:

- A `cd` command resulting in an error
- Any invalid command
- Authentication failed error
- Unable to connect to server error
- Connection aborted error
By default, in case of errors, `sftpg3` does not stop but instead will continue executing and return the last error message.

Invalid commands added in `--commands` will be ignored.

`overwrite [yes | no]`

Decides whether to overwrite existing destination file(s) (default: yes).

`progress-display [bar | line | no]`

Chooses the mode of displaying the progress during a file transfer operation. The default is `bar`, which shows a progress bar. Option `line` shows the progress information according to the settings made with the `progress-line-format` option. Option `no` disables progress display.

`progress-line-format=FORMAT_STRING`

Chooses what information will be shown on the progress line. Use this option when `--progress-display=line`. See the definitions of contents options in command: `get --progress-line-format`.

`progress-line-interval=seconds`

Defines how often the progress information is updated in line mode. The interval is given in seconds, and the default is 60 seconds.

`summary-display [no | yes | simple | bytes]`

Chooses the style of the file transfer summary data to be displayed after a file transfer operation. With the summary display, the progress bar data is also displayed by default. Do not use this option with `--statistics`.

See the options described for command: `get --summary-display`.

`summary-format=FORMAT_STRING`

Chooses the format and the contents of the summary. You can use this option when `--summary-display=yes`. Do not use this option with `--statistics`.

See the definitions of contents options in command: `get --summary-format`.

`streaming [yes | no | force | ext]`

Uses streaming in file transfer if the server supports it. Files smaller than `buffer_size_bytes` are not transferred using streaming. Use `force` with small files. Default: `yes`.

Use `ext` with z/OS hosts to enable direct MVS data set access. Use this option only when the file transfer is mainly used for mainframe data set transfers, as it can slow down the transfer of small files in other environments.

The `streaming=ext` option requires also the `checksum=no` option, because if checksums are calculated, the file transfer uses staging, which excludes streaming.
setext [extension...] 

Sets the file extensions that will be ASCII in the auto transfer mode. Normal zsh-fileglob regexps can be used in the file extensions.

setperm fileperm[:dirperm] 

Sets the default file or directory permission bits for upload. (Prefix fileperm with p to preserve permissions of existing files or directories.)

sget [options...] srcfile [dstfile] 

Transfers a single specified file from the remote end to the local end under the filename defined with dstfile. Directories are not copied. No wildcards can be used. Options are the same as for get.

site [none | name1=value1 name2=value2... ] 

Sets the file and data set parameters for the remote host. Parameters can be entered either one by one, or several parameters can be delimited by spaces or commas. Both long parameters and abbreviations can be used. When run without arguments, the site command outputs the list of entered parameters. Setting none resets all parameters.

The available parameters are:

- AUTOMOUNT=YES|NO|IMMED
- [NO]AUTOMOUNT [NO]AUTOM
- AUTORECALL=YES|NO
- [NO]AUTORECALL [NO]AUTOR
- BLKSIZE|B|BLOCKSI=size
- BLOCKS|BL
- CONDDISP|CO=CATLG|UNCATLG|KEEP|DELETE
- CYLINDERS|CY
- DATACLAS|DA=class
- DATASET_SEQUENCE_NUMBER|SEQNUM=number

- UNIT_COUNT UC UNC=number
- UNIT_PARALLEL UNP=YES NO
- VOLUME_COUNT VC VOLCNT=number
- VOLUMES VO VOL=vol1+vol2+

sput [options...] srcfile [dstfile]

Transfers a single specified file from the local end to the remote end under the filename defined with dstfile. Directories are not copied. No wildcards can be used. Options are the same as for get.

sunique [on] [off]

Stores files with unique names. If no option is specified, the command toggles the state of 'sunique'.

In case more than one of the transferred files have the same name, this feature adds a sequential number to the end of the repeated filename, for example: file.name, file.name1, and file.name2.

symlink targetpath linkpath

Creates symbolic link linkpath, which will point to targetpath.

type [ ascii | auto | binary | default ]

Sets file transfer type. If type is not specified, the current file transfer type is displayed.

ascii

Transfer file in ascii mode. See ascii for more information.
auto

Transfer file in auto mode. See auto for more information.

binary

Transfer file in binary mode. See binary for more information.

default

Transfer file in binary mode. This mode is identical to binary except that when the server is Tectia Server for IBM z/OS, no extra parameters are specified for the server. See binary for more information.

verbose

Enables verbose mode (identical to the debug 2 command). You may later disable verbose mode by debug disable.

help [topic]

If topic is not given, lists the available topics. If topic is given, outputs available online help about the topic.

helpall

Outputs available online help about all topics.

Command Interpretation

sftpg3 understands both backslashes (\) and quotation marks ("""\"""") on the command line. A backslash can be used for ignoring the special meaning of any character in the command-line interpretation. It will be removed even if the character it precedes has no special meaning.

When specifying filenames that contain spaces, enclose them in quotation marks.

Note

Commands get . and put . will get or put every file in the current directory and possibly they overwrite files in your current directory.

sftpg3 supports wildcard characters (also known as glob patterns) given to commands chmod, lchmod, ls, lls, rm, lrm, get, and put.

Command-Line Editing (Unix)

On Unix, the following key sequences can be used for command-line editing:

- Tectia® Client 6.4 User Manual
- © 1995–2021 SSH Communications Security Corporation
Ctrl-Space
    Set mark.

Ctrl-A
    Go to the beginning of the line.

Ctrl-B
    Move the cursor one character to the left.

Ctrl-D
    Erase the character to the right of the cursor, or exit the program if the command line is empty.

Ctrl-E
    Go to the end of the line.

Ctrl-F
    Move the cursor one character to the right.

Ctrl-H
    Backspace.

Ctrl-I
    Tab.

Ctrl-J
    Enter.

Ctrl-K
    Delete the rest of the line.

Ctrl-L
    Redraw the line.

Ctrl-M
    Enter.

Ctrl-N
    Move to the next line.

Ctrl-P
    Move to the previous line.
Ctrl-T
   Toggle two characters.

Ctrl-U
   Delete the line.

Ctrl-W
   Delete a region (the region's other end is marked with Ctrl-Space).

Ctrl-X
   Begin an extended command.

Ctrl-Y
   Yank deleted line.

Ctrl-
   Undo.

Ctrl-X Ctrl-L
   Lower case region.

Ctrl-X Ctrl-U
   Upper case region.

Ctrl-X Ctrl-X
   Exchange cursor and mark.

Ctrl-X H
   Mark the whole buffer.

Ctrl-X U
   Undo.

Esc Ctrl-H
   Backwards word delete.

Esc Delete
   Backwards word delete.

Esc Space
   Delete extra spaces (leaves only one space).
Esc <
  Go to the beginning of the line.

Esc >
  Go to the end of the line.

Esc @
  Mark current word.

Esc A
  Go back one sentence.

Esc B
  Go back one word.

Esc C
  Capitalize current word.

Esc D
  Delete current word.

Esc E
  Go forward one sentence.

Esc F
  Go forward one word.

Esc K
  Delete current sentence.

Esc L
  Change current word to lower case.

Esc T
  Transpose words.

Esc U
  Change current word to upper case.

Delete
  Backspace.
Filename Support

Different operating systems allow different character sets in filenames. On Unix, some of the special characters are allowed in filenames, but on Windows, the following characters are not allowed:

\ / : * ? " < > |

The sftpg3 command-line tool (both as an interactive and in a batch file) follows the syntax and semantics of Unix shell command-line also on the Windows platform, except that the escape character is ~ (tilde).

When you transfer files that have special characters in the filename (for example `unixfilename*?.txt`) from a Unix server to Windows, you need to provide the files with new names that are acceptable on Windows.

The sftpg3 command-line client includes two versions of the get command:

The get command can be used to transfer several files at the same time, but it is not possible to define target filenames. Note that if there are special characters in the filenames, you need to rename the files already on Unix so that the names are acceptable also on Windows.

The sget command is used to transfer one file at a time, and it allows you to define a new name for the destination file. Use it to make the name acceptable on Windows. The command sequence is as follows:

```
$ sftpg3
sftp> open user@server
sftp> sget "filename.txt" windowsfilename.txt
```

Escaping special characters

In the sftpg3 command, the following characters have a special meaning, and they need to be escaped in commands that take filenames as arguments:

* asterisk is a wildcard character for any number of any characters

? question mark is a wildcard for any single character

"" quotation marks are placed around strings that are to be taken 'as is'

\ backslash is an escape character on Unix

~ tilde is an escape character on Windows

The escape character tells the sftpg3 command to treat the next character "as is" and not to assume any special meaning for it. The escape character is selected according to the operating system of the local machine.

Note that the \ and ~ characters are special characters themselves, and if they are present in the filename, an escape character must be placed in front of them, too. Therefore, if you need to enter a filename containing \ in Unix or ~ in Windows to any of the sftpg3 commands, add the relevant escape character to it:
\ on Unix

\ on Windows

When a filename or part of a filename is placed within the quotation marks "", the sftpg3 command interprets the quoted part 'as is', and none of the characters within the quote are interpreted as wildcards or as any other special characters.

However, on Unix a quotation mark " can also be part of a filename. If you need to enter the " character in a filename, you must add the escape character in front of it both on Unix and on Windows.

For example, to enter a file named file-"name".txt into a command on Windows, enter the following command:

```
sftp> sget "file-"name".txt" filename.txt
```

See the examples below to learn how the escape characters are used in the Tectia sftpg3 commands, and how to enter filenames with special characters in different operating systems.

Examples of filenames in the sftpg3 commands:

The following filenames are valid in Unix, but they need escape characters in the commands:

```
file\|name.txt
file="name".txt
file?name.txt
file*name.txt
file\name.txt
file - name.txt
file~name.txt
```

When using the sftpg3 command-line tool on Unix, enter the above mentioned filenames in the following formats:

```
file\|name.txt      or  "file\|name.txt"
file-"name".txt    or  "file-"name".txt"
file?name.txt      or  "file?name.txt"
file*name.txt      or  "file*name.txt"
file\name.txt      or  "file\name.txt"
file - name.txt    or  "file - name.txt"
file~name.txt      or  "file~name.txt"
```

Example commands on Unix:

```
sftp> get "file*name.txt"
```

```
sftp> sget "file*name.txt" newfilename.txt
```

When using the sftpg3 command on Windows, enter the above mentioned Unix filenames in the following formats:

```
file~|name.txt     or  "file~|name.txt"
file-~"name~".txt  or  "file-~"name~".txt"
file~?name.txt     or  "file?name.txt"
file~*name.txt     or  "file*name.txt"
```

© 1995–2021 SSH Communications Security Corporation

Tectia® Client 6.4 User Manual
Example command sequence on Windows:

```
> sftpg3 open user@server
sftp> get "file name.txt"
sftp> sget "file*name.txt" filename.txt
```

### Environment Variables

`sftpg3` uses the following environment variables:

**SSH_SFTP_BATCH_FILE=**`startup_batch_file`

Defines the path to the `sftpg3` startup batch file. The file is run and the `sftpg3` commands defined in the file are executed each time `sftpg3` is started.

If this variable is not defined, `sftpg3` looks for a startup batch file named `ssh_sftp_batch_file` in the user-specific directory `$HOME/.ssh2/` on Unix or `%APPDATA%\SSH\` on Windows.

Note that if this variable is defined but the file is missing or cannot be accessed, `sftpg3` fails to start.

**SSH_SFTP_CHECKSUM_MODE=**`yes|no|md5|md5-force|sha1|sha1-force|checkpoint`

Defines the setting for comparing checksums. For more information on the available values, see the `checksum`.

**SSH_SFTP_SHOW_BYTE_COUNT=**`yes|no`

If this variable is set to `yes`, the number of transferred bytes is shown after successful file transfer. Also the names of source and destination files are shown. The default is `no`.

**SSH_SFTP_STATISTICS=**`yes|no|simple`

If this variable is set to `yes` (default), normal progress bar is shown while transferring the file. If it is set to `no`, progress bar is not shown. If it is set to `simple`, file transfer statistics are shown after the file has been transferred.

### Exit Values

`sftpg3` returns the following values based on the result of the operation:

0  Operation was successful.
1  Internal error.
2  Connection aborted by the user.
3  Destination is not a directory, but a directory was specified by the user.
4  Connecting to the host failed.
In batch mode, `sftpg3` returns the value 0 only if no errors occurred during the execution. A failure to change the current working directory, a failure to establish a connection, or a connection loss during batch operation cause `sftpg3` to abort. Other errors are reported to stderr and the last error value is returned as the exit value of the `sftpg3` process.

**Examples**

Open a `sftpg3` session with the remote end connected to the server defined in the connection profile `profile1` in the `ssh-broker-config.xml` file (the local end is initially connected to the file system of the SFTP client host):

```bash
$ sftpg3 profile1
```

Run `sftpg3` in batch mode:

```bash
$ sftpg3 -B batch.txt
```

Example contents of the batch file `batch.txt` are shown below. Non-interactive authentication methods are used and the server host keys have been stored beforehand:

```
lopen user@unixserver.example.com
open user@winserver.example.com
binary
lcd backup
cd c:/temp
get --force-lower-case Testfile-X.bin
lchmod 700 testfile-x.bin
quit
```

The example batch file opens the local end of the connection to a Unix server and the remote end to a Windows server, and sets the transfer mode to binary. It changes to local directory `backup` and remote directory `C:\Temp`, and copies a file from the remote directory to the local directory. The filename is changed to lower-case characters (`testfile-x.bin`). After transfer, the file permissions are changed to allow the user full rights and others no rights.
**ssh-translation-table**

`ssh-translation-table` — Secure Shell Translation Table

**Synopsis**

`ssh-translation-table [options...]`

[filename]

**Description**

`ssh-translation-table` (`ssh-translation-table.exe` on Windows) is a utility program that generates translation tables for coded character set (CCS) conversions. `ssh-translation-table` stores the translation table in `filename`. If `filename` is not given, `ssh-translation-table` writes the translation table to standard output.

**Options**

The following options are available:

- `-b, --binary`
  
  Use the z/OS-specific binary file format.

- `-f, --from=CODESET`
  
  Specify the source code set of the inbound conversion, which is also the target code set of the outbound conversion. The default value is `ISO8859-1`. For example:

  ```
  --from ISO8859-15
  ```

- `-t, --to=CODESET`
  
  Specify the target code set of the inbound conversion, which is also the source code set of the outbound conversion. The default value is `IBM-1047,swaplfnl` if the underlying implementation is ICU, otherwise `IBM-1047`. For example:

  ```
  --to IBM-037
  ```

- `-l, --list-charsets`
  
  List available character sets. Note that all character sets are not single byte character sets. Only single byte character sets can be used.

- `-D, --debug=LEVEL`
  
  Sets the debug level. `LEVEL` is a number from 0 to 99, where 99 specifies that all debug information should be displayed. This should be the first argument on the command line.

- `-h, --help`
  
  Displays a short summary of command-line options and exits.
Translation Table

A translation table is a file containing two tables describing the character conversion, the inbound table and the outbound table. Each table consists of 256 target values.

In Tectia File Transfer, the inbound table is used when converting data from the line to the data set. The outbound table is used when converting data from a file and sending the data out on the line.

The binary format, which is z/OS specific, consists of three 256 byte fields. The first is a comment in EBCDIC, which is ignored in the conversion software, the second is the inbound table and the third is the outbound table.

The text format can have interspersed comments. The target values are in hexadecimal.

A table is a list of 256 values represented as two hexadecimal characters (from 00 to FF). The position of the value is the index for conversion. The first position, i.e. position 00, represents the converted value for byte value of 0.

The hexadecimal values in the tables are case-insensitive. So values 0a and 0A are the same. Also, it is possible to add comments into the file. The comment starts with character ‘#’. Everything after that until end of line is treated as comment and ignored. Also all white spaces are ignored.

Note

Only single byte translations are supported with translation tables.

Here is an example translation table generated with command ssh-translation-table:

```
# SSH TRANSLATION TABLE FILE FORMAT VERSION 1.0
#***************************************************************************
#
# This file is an example translation table that can be used to
# translate data from 'ISO8859-1' to 'IBM-1047,swaplfnl' while reading
# from a file or from 'IBM-1047,swaplfnl' to 'ISO8859-1' while writing
# to a file.
#
# The format of translation table file is following:
#
# - White spaces are ignored.
# - Everything after '#' character until end of line is a comment
#   that is ignored.
# - The first table is used when writing data to a file.
# - The second table is used when reading data from a file.
# - Both tables must exist.
# - Table is a simple hexadecimal representation of the
#   translation. Each value is represented as two hexadecimal
#   characters. The first line gives the values in table
#   positions 0-15 (00-0F), the second line 16-31 (10-1F)
#   and so on.
#
# Note: Only single byte translations are supported.
#***************************************************************************
```

© 1995–2021 SSH Communications Security
Corporation

Tectia® Client 6.4 User Manual
### Inbound (network to file) translation table:

```
# IBM-1047,swaplfnl -> ISO8859-1

<table>
<thead>
<tr>
<th>IBM-1047</th>
<th>ISO8859-1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1-2-3-4-5-6-7-8-9-A-B-C-D-E-F</td>
<td></td>
</tr>
</tbody>
</table>
```

### Outbound (file to network) translation table:

```
# ISO8859-1 -> IBM-1047,swaplfnl

<table>
<thead>
<tr>
<th>IBM-1047</th>
<th>ISO8859-1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1-2-3-4-5-6-7-8-9-A-B-C-D-E-F</td>
<td></td>
</tr>
</tbody>
</table>
```

---

**Note**

When ICU libraries are used for generating ASCII to EBCDIC translation tables, ,swaplfnl must be added to the EBCDIC codepage name so that ASCII line feed characters (0A) are correctly translated to EBCDIC newline characters (15).

In order to create a custom translation table, first create a translation table with `ssh-translation-table` and then edit it with any text editor.
Environment Variables

SSH_CHARSET_CONV

The full pathname of the Tectia conversion DLL. Only required if `ssh-translation-table` or the conversion DLL are not in the installation directories. Here is an example of the pathname:

```
SSH_CHARSET_CONV=/opt/tectia/lib/shlib/i18n_iconv.so
```
**ssh-keygen-g3**

ssh-keygen-g3 — authentication key pair generator

**Synopsis**

```
ssh-keygen-g3 [ options ...]
[ key1 key2 ...]
```

**Description**

**ssh-keygen-g3 (ssh-keygen-g3.exe on Windows)** is a tool that generates and manages authentication keys for Secure Shell. Each user wishing to use a Secure Shell client with public-key authentication can run this tool to create authentication keys. Additionally, the system administrator can use this to generate host keys for the Secure Shell server. This tool can also convert OpenSSH public or private keys to the Tectia key format, or, from Tectia key format to openSSH format. Tectia public keys use the Secure Shell (SSH) Public Key File Format (RFC 4716).

By default, if no path for the key files is specified, the key pair is generated under the user’s home directory ($HOME/.ssh2 on Unix, "%APPDATA%\SSH\UserKeys" on Windows). If no file name is specified, the key pair is likewise stored under the user’s home directory with such file names as id_rsa_2048_a and id_rsa_2048_a.pub.

When specifying file paths or other strings that contain spaces, enclose them in quotation marks (" ").

**Options**

The following options are available:

- **-1 file**
  
  Converts a key file from the SSH1 format to the SSH2 format. Note: "1" is number one (not letter L).

- **-7 file**
  
  Extracts certificates from a PKCS #7 file.

- **-b bits**
  
  Specifies the length of the generated key in bits. The allowed and default lengths for different key types are:

  - **DSA/RSA**: allowed 512 to 65536 bits, default 2048 bits
  - **ECDSA**: allowed 256, 384 and 521 bits, default 256 bits
  - **Ed25519**: allowed/default 512 bits
Appendix C Command-Line Tools and Man Pages

-B num

Specifies the number base for displaying key information (default: 10).

-c comment

Specifies a comment string for the generated key.

-D file

Derives the public key from the private key file.

-e file

Edits the specified key. Makes ssh-keygen-g3 interactive. You can change the key's passphrase or comment.

-F, --fingerprint file

Dumps the fingerprint and type (RSA, DSA, ECDSA or Ed25519) of the given public key. By default, the fingerprint is given in the SSH Babble format, which makes the fingerprint look like a string of "real" words (making it easier to pronounce). The output format can be changed with the --fingerprint-type option.

The following options can be used to modify the behavior of this option: --fingerprint-type, --hash, --hostkeys-directory, --known-hosts, --rfc4716.

-F, --fingerprint host_ID

Dumps the location, fingerprint and type (RSA, DSA, ECDSA or Ed25519) of the locally stored host key(s) identified with the given host_ID. The host_ID is a host name or string "host#port".

The following options can be used to modify the behavior of this option: --fingerprint-type, --hash, --hostkeys-directory, --known-hosts, --rfc4716.

-H, --hostkey

Stores the generated key pair in the default host key directory (/etc/ssh2 on Unix, "<INSTALLDIR>\SSH Tectia Server" on Windows). Specify the -P option to store the private key with an empty passphrase.

-i file

Loads and displays information on the key file.

-k file

Converts a PKCS #12 file to an SSH2-format certificate and private key.

-m, --generate-moduli-file

-p passphrase

Specifies the passphrase for the generated key.

-P

Specifies that the generated key will be saved with an empty passphrase.

**Note**

In FIPS mode, due to a FIPS regulation which forbids exporting unencrypted private keys out of the FIPS module, it is not possible to generate user keys without a passphrase.

-q, --quiet

Hides the progress indicator during key generation.

-r file

Adds entropy from file to the random pool. If file contains 'relatively random' data (i.e. data unpredictable by a potential attacker), the randomness of the pool is increased. Good randomness is essential for the security of the generated keys.

-t dsa | rsa | ecdsa | ed25519

Selects the type of the key. Valid values are rsa (default), dsa, ecdsa, and ed25519.

-x file

Converts a private key from the X.509 format to the SSH2 format.

--append [ yes | no ]

Appends the keys. Optional values are yes and no. The default is yes to append.

--copy-host-id host_ID destination

Copies the host identity to the specified destination directory.

The following options can be used to modify the behavior of this option: --append, --hostkeys-directory, --known-hosts, --overwrite.

If --hostkey-file is given, the file is treated as a normal host identity file used by the Connection Broker, and its contents will be copied to the destination directory.

--delete-host-id host_ID

Deletes the host key of the specified host ID. The host_ID is a host name or string "host#port".

The following options can be used to modify the behavior of this option: --host-key-file, --hostkeys-directory, --known-hosts.
--fingerprint-type  babble|babble-upper|pgp-2|pgp-5|hex|hex-upper|base64

Specifies the output format of the fingerprint. If this option is given, the -F option and the key file name must precede it. The default format is babble.

See the section called “Examples” for examples of using this option.

--fips-mode

Generates the key using the FIPS mode for the cryptographic library.

Note

Ed25519 keys are not available in FIPS mode.

On Linux, Windows, Solaris and HP-UX Itanium the OpenSSL cryptographic library version 1.0.2a is used and in the FIPS mode (conforming to FIPS 186-3) keys of the following lengths can be generated:

- DSA keys: 1024, 2048 and 3072 bits
- RSA keys: $n \times 512$ bits, where $2 \leq n \leq 24$ (that is, 1024, 1536, ..., 11776, and 12288 bits)
- ECDSA keys: 256, 384 and 521 bits

On HP-UX PA-RISC and IBM AIX the OpenSSL cryptographic library version 0.9.8 is used and in the FIPS mode (conforming to FIPS 186-2) DSA keys of 1024 bits and RSA keys of 1024 to 16384 bits can be generated. ECDSA keys cannot be generated.

The keys must have non-empty passphrases.

By default (if this option is not given), the key is generated using the standard mode for the cryptographic library.

--fips-crypto-dll-path  PATH

Specifies the location of the FIPS cryptographic DLL.

--hash  md5|sha1|sha256

Specifies the digest algorithm for fingerprint generation. Valid options are md5, sha1, and sha256.

--hostkey-file  file

When copying, uses the given file as the source host key, instead of autodetecting the location. When deleting, only deletes from the given location. If the specified file does not contain identities for the specified host, does nothing.

--hostkeys-directory  directory

Specifies the directory for known host keys to be used instead of the default location.
--import-public-key infile [outfile]

Attempts to import a public key from infile and store it to outfile in the format specified by --key-format parameter. If outfile is not given, it will be requested. The default output format is SSH2 native format.

--import-private-key infile [outfile]

Attempts to import a private key from infile and store it to outfile in the format specified by --key-format parameter. If outfile is not given, it will be requested. The default output format is SSH2 native private key format.

--import-ssh1-authorized-keys infile outfile

Imports an SSH1-style authorized_keys file infile and generates an SSH2-style authorization file outfile, and stores the keys from infile to generated files into the same directory with outfile.

--key-format format

Output key format: secsh2, pkcs1, pkcs8, pkcs12, openssh2, or openssh2-aes.

--key-hash hash

This option can be used for other than Tectia key formats. Specifies the hash algorithm to be used in passphrase-based private key derivation. The default value is sha1. Other supported algorithms are sha224, sha256, sha384, and sha512. Note that all key formats do not support all hash algorithms.

--known-hosts file

Uses the specified known hosts file. Enables fetching fingerprints for hosts defined in an OpenSSH-style known-hosts file. Using this option overrides the default locations of known_hosts files (/etc/ssh/ssh_known_hosts and $HOME/.ssh/known_hosts). Giving an empty string will disable known-hosts usage altogether.

--moduli-file-name file

Writes the moduli generated for Diffie-Hellman group exchange to file. (The default file name for option -m is secsh_dh_gex_moduli.)

--overwrite [ =yes | no ]

Overwrite files with the same file names. The default is to overwrite.

--rfc4716

Displays the fingerprint in the format specified in RFC4716. The digest algorithm (hash) is md5, and the output format is the 16-bytes output in lowercase HEX separated with colons (:).

--set-hostkey-owner-and-dacl file

On Windows, sets the correct owner and DACL (discretionary access control list) for the host key file. This option is used internally when a host key is generated during Tectia Server installation.
Appendix C Command-Line Tools and Man Pages

-V

Displays version string and exits.

-h, --help, -?

Displays a short summary of command-line options and exits.

Examples

Create a 3072-bit RSA key pair using the cryptographic library in the FIPS mode and store the key pair in the default user key directory with file names \texttt{newkey} and \texttt{newkey.pub}:

\begin{verbatim}
$ ssh-keygen-g3 --fips-mode -b 3072 newkey
\end{verbatim}

Convert an SSH1 key \texttt{oldkey} to SSH2 format:

\begin{verbatim}
$ ssh-keygen-g3 -l oldkey
\end{verbatim}

Display the fingerprint of a server host public key in SSH babble (default) format:

\begin{verbatim}
$ ssh-keygen-g3 -F hostkey.pub
Fingerprint for key:
keneh-fyvam-sotaf-gutuv-rahih-kipod-poten-byfam-hufeh-tydym-syxex
\end{verbatim}

Display the fingerprint of a server host public key in hex format:

\begin{verbatim}
$ ssh-keygen-g3 -F hostkey.pub --fingerprint-type=hex
Fingerprint for key:
25533b8c7734f6eb1556ea2ab4900d854d5088c
\end{verbatim}

Convert a private key into openSSH2-AES format:

\begin{verbatim}
$ ssh-keygen-g3 -p <password> --key-format openssh2-aes \ 
--import-private-key <source_key_file> <destination_key_file>
\end{verbatim}

Note: if the private key file that is being converted is encrypted with a passphrase, the passphrase must be provided with the ‘-p’ option.

Convert a Tectia public key \texttt{tectikey.pub} to an OpenSSH public key \texttt{openshkey.pub}:

\begin{verbatim}
$ ssh-keygen-g3 --key-format openssh2 --import-public-key \ 
tectikey.pub openshkey.pub
\end{verbatim}

Generate moduli file \texttt{dhgex-moduli} for Diffie-Hellman group exchange:

\begin{verbatim}
$ ssh-keygen-g3 -m --moduli-file-name dhgex-moduli
\end{verbatim}
ssh-keyfetch

ssh-keyfetch — Host key tool for the Secure Shell client

Synopsis

ssh-keyfetch [options...] [host]

Description

ssh-keyfetch (ssh-keyfetch.exe on Windows) is a tool that downloads server host keys and optionally sets them as known host keys for the Secure Shell client. It is typically used by the system administrator during the initial setup phase.

By default the host key is fetched from the server and saved in file key_host_port.suffix in the current directory.

Options

The following options are available:

-a, --set-trusted

Instead of writing the public key to a file, add the public key as a known host key to the user-specific directory: $HOME/.ssh2/hostkeys (%APPDATA%\SSH\HostKeys on Windows). This option cannot be combined with -C or -K.

⚠️ Caution

When ssh-keyfetch is run with the -a option, it accepts the received host keys automatically without prompting the user. You should verify the validity of keys by verifying the key fingerprints after receiving them or you risk being subject to a man-in-the-middle attack.

To validate the host key, obtain the host key fingerprint from a trusted source (for example by calling the server administrator) and verify it against the output from command:

```
ssh-keygen-g3 --fingerprint <hostname>
```

-A, --fetch-any

Probe for and fetch either server public key or certificate.

-C, --fetch-certificate

Probe for and fetch the server certificate only.
-d, --debug debug-level

Enable debugging.

-D, --debug-default

Enable debugging with default level.

-f, --filename-format nameformat

Filename format for known host keys. Accepted values are plain and hashed. The default is plain.

-F, --fingerprint-type [=babble|babble-upper|pgp-2|pgp-5|hex|hex-upper|base64]

Public key fingerprint type for fingerprints displayed in messages and log. Most popular types are babble (the SSH babble format) and hex. The default is babble. See also the option --rfc4716.

-H, --hash [md5|sha1|sha256]

Specifies the digest algorithm for fingerprint generation. Valid options are md5, sha1, and sha256.

-K, --kex-key-formats typelist

Explicitly specify the host-key types accepted in protocol key exchange. For experts only. See RFC 4253 for details.

-l, --log

Report successfully received keys in log format. The log format consists of one line per key, six fields per line. The fields are:

• accept|save
• replace|append
• hostname
• ip-port
• user-id
• key-file-path
• fingerprint

-o, --output-file output-file

Write result to output-file. A minus sign ("-") denotes standard output.

-O, --output-directory output-dir

Write result to output-dir. The default is the current directory.
-p, --port port

    Server port (default: 22).

-\P, --fetch-public-key

    Probe for and fetch the server public key only. This is the default behaviour.

-q, --quiet

    Quiet mode, report only errors.

-R, --rfc4716

    Displays the public key fingerprints in the format specified in RFC 4716. The digest algorithm (hash) is md5, and the output format is the 16-bytes output in lowercase HEX separated with colons (:) goodness.

-S, --proxy-url socks-url

    Specifies the SOCKS server to use.

-t, --timeout timeout

    Connection timeout in seconds (default: 10 seconds).

--append [ -y es | no ]

    Instead of appending a new host key, overwrite the existing known host keys for this host. Optional values are yes and no. The default is to append.

-V, --version

    Displays version string and exits.

**Environment Variables**

**SSH_SOCKS_SERVER**

    The address of the SOCKS server used by ssh-keyfetch.

**Examples**

Connect to the server through a SOCKS proxy:

```bash
$ ssh-keyfetch -S socks://fw.example.com:1080/10.0.0.0/8 server.outside.example
Public key from server.outside.example:22 saved.
File: server.outside.example.pub
```

Accept the server key as a known key for Tectia Client and report in the more rigid log format:

```bash
$ ssh-keyfetch -a -l newhost
```
Accepted newhost 22 testuser /home/testuser/.ssh2/hostkeys/key_22_newhost.pub
xigad-hozuf-kykek-vojid-dumid-bydop-mulym-zegar-nybuv-muled-syxyx

Accept the server key as a known key for Tectia Client and store the key to global configuration hostkeys directory:

$ ssh-keyfetch -a --output-directory /etc/ssh2/hostkeys
Accepted newhost 22 testuser /etc/ssh2/hostkeys/key_22_anotherhost.pub
bydop-mulym-zegar-nybuv-muled-syxyx-xigad-hozuf-kykek-vojid-dumid

Accept the server key as a known key for Tectia Client and use an uninformative hash as the filename for the stored known key:

$ ssh-keyfetch -f hashed -a newhost
Public key from newhost:22 accepted as trusted hostkey.
File: /home/testuser/.ssh2/hostkeys/keys_420b23ca959ab165e52e117a90bbaa89d92f5c35
Fingerprint: xigad-hozuf-kykek-vojid-dumid-bydop-mulym-zegar-nybuv-muled-syxyx

Accept RSA, ECDSA and ed25519 server keys as a known key for Tectia Client:

$ for t in ecdsa ed25519 rsa; do
  ssh-keyfetch --set-trusted -k $t newhost
done
Public key from newhost accepted as trusted hostkey.
File: /home/testuser/.ssh2/hostkeys/key_22_newhost.pub
Public key from newhost:22 accepted as trusted hostkey.
File: /home/testuser/.ssh2/hostkeys/key_22_newhost.pub
Fingerprint: xuzib-sehat-pemys-zulor-foran-tizur-repyh-boryd-nogeb-refip-raxax
Public key from newhost:22 accepted as trusted hostkey.
File: /home/testuser/.ssh2/hostkeys/key_22_newhost.pub
Fingerprint: xifon-sorer-pysys-vumab-mosuz-pefor-pevab-givaz-feguc-nyven-lexux

Fetch the X.509 certificate of the server running in port 222 and display the content with ssh-certview:

$ ssh-keyfetch -C -p 222 -o newhost | ssh-certview -
Certificate =
  SubjectName = <C=FI, O=SSH, OU=DEV, CN=newhost.ssh.com>
  IssuerName = <C=FI, O=SSH, CN=Sickle CA>
  SerialNumber= 24593438
  Validity =
    NotBefore = 2007 Sep 13th, 15:10:00 GMT
    NotAfter = 2008 Sep 12th, 15:10:00 GMT
  PublicKeyInfo =
    PublicKey =
      Algorithm = RSA
      Modulus n (1024 bits) :
...
  Fingerprints =
SHA-1 =

This explicit key exchange type list is equivalent to specifying option -A:

$ ssh-keyfetch -K
ssh-rsa-sha512@ssh.com,ssh-rsa-sha384@ssh.com,ssh-rsa-sha256@ssh.com,ssh-rsa-sha224@ssh.com,...
Public key from newhost:22 saved.
File: key_newhost_22.pub
Fingerprint:
xigad-hozuf-kykek-vogid-dumid-bydop-mulym-zegar-nybuv-muled-syxyx
**ssh-cmpclient-g3**

*ssh-cmpclient-g3 — CMP enrollment client*

### Synopsis

```
ssh-cmpclient-g3 command [options] access [name]
```

Where command is one of the following:

- `INITIALIZE` psk|racerts keypair template
- `ENROLL` certs|racerts keypair template
- `UPDATE` certs [keypair]
- `POLL` psk|certs|racerts id
- `RECOVER` psk|certs|racerts template
- `REVOKE` psk|certs|racerts template
- `TUNNEL` racerts template

Most commands can accept the following options:

- `-B` Perform key backup for subject keys.
- `-o prefix` Save result into files with given prefix.
- `-O filename` Save the result into the specified file.
  If there is more than one result file, the remaining results are rejected.
- `-C file` CA certificate from this file.
- `-S url` Use this SOCKS server to access the CA.
- `-H url` Use this HTTP proxy to access the CA.
- `-E` PoP by encryption (CA certificate needed).
- `-v num` Protocol version 1|2 of the CA platform. Default is 2.
- `-y` Non-interactive mode. All questions answered with 'y'.
- `-N file` Specifies a file to stir to the random pool.
- `-d level` Set debug level.
- `-Z provspec` Specifies external key provider for the private key.
  The format of provspec is "providername:initstring".

The following identifiers are used to specify options:

- `psk` -p refnum:key (reference number and pre-shared key)
  -p file (containing refnum:key)
  -i number (iteration count, default 1024)
- `certs` -c file (certificate file) -k url (private-key URL)
- `racerts` -R file (RA certificate file) -k url (RA private-key URL)
- `keypair` -P url (private-key URL)
- `id` -I number (polling ID)
- `template` -T file (certificate template)
  -s subject-ldap[type=value]
  -u key-usage-name;key-usage-name
  -U extended-key-usage-name;extended-key-usage-name
- `access` URL where the CA listens for requests.
- `name` LDAP name for the issuing CA (if -C is not given).
Key URLs are either valid external key paths or in the format:
   "generate://savetype:passphrase@keytype:size/save-file-prefix"
   "file://passphrase/relative-key-file-path"
   "file:relative-key-file-path"
   "any-key-file-path"

The key generation "savetype" can be:
- ssh2, secsh2, secsh (Secure Shell 2 key type)
- ssh1, secsh1 (legacy Secure Shell 1 key type)
- pkcs1 (PKCS #1 format)
- pkcs8s (passphrase-protected PKCS #8, "shrouded PKCS #8")
- pkcs8 (plain-text PKCS #8)
- x509 (Tectia-proprietary X.509 library key type)

-h Prints usage message.
-F Prints key usage extension and keytype instructions.
-e Prints command-line examples.

Description

The ssh-cmpclient-g3 command-line tool (ssh-cmpclient-g3.exe on Windows) is a certificate enrollment client that uses the CMP protocol. It can generate an RSA or DSA public-key pair and get certificates for their public components. CMP is specified by the IETF PKIX Working Group for certificate life-cycle management, and is supported by some CA platforms, such as RSA Keon.

Commands

The ssh-cmpclient-g3 command-line command keywords are listed below. Shorthands longer than three letters can be used to identify the command. The commands are case-insensitive. The user must specify the CA address URL for each command. Here the term "user" refers to a user, program, or hardware device.

INITIALIZE

Requests the user’s initial certificate. The request is authenticated using the reference number and the corresponding key (PSK) received from the CA or RA using some out-of-band mechanism.

The user must specify the PSK, the asymmetric key pair, and a subject name.

ENROLL

Requests a new certificate when the user already has a valid certificate for the key. This request is similar to initialize except that it is authenticated using public-key methods.

POLL

Polls for a certificate when a request was not immediately accepted.

UPDATE

Requests an update of an existing certificate (replacement). The issued certificate will be similar to the existing certificate (names, flags, and other extensions). The user can change the key, and the
validity times are updated by the CA. This request is authenticated by a valid existing key pair and a certificate.

RECOVER

Requests recovery of a backed-up key. This request is authenticated either by PSK-based or certificate-based authentication. The template describes the certificate whose private key has already been backed up and should be recovered. Users can only recover keys they have backed up themselves.

REVOKE

Requests revocation for a key specified in the template. Authentication of the request is made using a PSK or a certificate belonging to the same user as the subject of revocation.

TUNNEL

Operates in RA tunnel mode. Reads requests and optionally modifies the subject name, alternative names, and extensions based on the command line. Approves the request and sends it to the CA.

Options

The `ssh-cmpclient-g3` command-line options are listed below. Note that when a file name is specified, an existing file with the same name will be overwritten. When specifying subject names or other strings that contain spaces, enclose them in quotation marks ("").  

-B

Requests private key backup to be performed for the initialize, enroll, and update commands.

-o prefix

Saves resulting certificates and CRLs into files with the given `prefix`. The prefix is first appended by a number, followed by the file extension .crt or .crl, depending on the type of object.

-O filename

Saves the result into the specified absolute filename. If there is more than one result file, the remaining results are rejected.

-C file

Specifies the file path that contains the CA certificate. If key backup is done, the file name must be given, but in most cases the LDAP name of the CA can be given instead.

-S url

Specifies the SOCKS URL if the CA is located behind a SOCKS-enabled firewall. The format of the URL is: socks://[username@]server[:port][/network/bits[,network/bits]]

-H url

Uses the given HTTP proxy server to access the CA. The format of the URL is: http://server[:port]/
-E

Performs encryption proof of possession if the CA supports it. In this method of PoP, the request is not
signed, but instead the PoP is established based on the ability to decrypt the certificates received from
the CA. The CA encrypts the certificates with the user's public key before sending them to the user.

-v num

Selects the CMP protocol version. This is either value 1, for an RFC 2510-based protocol, or 2 (the
default) for CMPv2.

-N file

Specifies a file to be used as an entropy source during key generation.

-d level

Sets the debug level string to level.

-Z provspec

Specifies the external key provider for the private key. Give provspec in the format
"providername:initstring".

The usage line uses the following meta commands:

psk

The reference number and the corresponding key value given by the CA or RA.

-p refnum:key|file

refnum and key are character strings shared among the CA and the user. refnum identifies the
secret key used to authenticate the message. The refnum string must not contain colon characters.

Alternatively, a filename containing the reference number and the key can be given as the
argument.

-i number

number indicates the key hashing iteration count.

certs

The user's existing key and certificate for authentication.

-k url

URL specifying the private key location. This is an external key URL whose format is specified
in the section called “Synopsis”.

© 1995–2021 SSH Communications Security

Tectia® Client 6.4 User Manual

Corporation
-c file

Path to the file that contains the certificate issued to the public key given in the -k option argument.

racerts

In RA mode, the RA key and certificate for authentication.

-k url

URL specifying the private key location. This is an external key URL whose format is specified in the section called “Synopsis”.

-R file

Path to the file that contains the RA certificate issued to the public key given in the -k option argument.

keypair

The subject key pair to be certified.

-P url

URL specifying the private key location. This is an external key URL whose format is specified in the section called “Synopsis”.

id

Polling ID used if the PKI action is left pending.

-I number

Polling transaction ID number given by the RA or CA if the action is left pending.

template

The subject name and flags to be certified.

-T file

The file containing the certificate used as the template for the operation. Values used to identify the subject are read from this, but the user can overwrite the key, key-usage flags, or subject names.

-s subject-ldap[;type=value]*

A subject name in reverse LDAP format, that is, the most general component first, and alternative subject names. The name subject-ldap will be copied into the request verbatim.

A typical choice would be a DN in the format "C=US,O=SSH,CN=Some Body", but in principle this can be anything that is usable for the resulting certificate.
The possible type values are ip, email, dn, dns, uri, and rid.

-u key-usage-name[;key-usage-name] *

Requested key usage purpose code. The following codes are recognized: digitalSignature, nonRepudiation, keyEncipherment, dataEncipherment, keyAgreement, keyCertSign, cRLSign, encipherOnly, decipherOnly, and help. The special keyword help lists the supported key usages which are defined in RFC 3280.

-U extended-key-usage-name[;extended-key-usage-name] *

Requested extended key usage code. The following codes, in addition to user-specified dotted OID values are recognized: serverAuth, clientAuth, codeSigning, emailProtection, timeStamping, ikeIntermediate, and smartCardLogon.

access

Specifies the CA address in URL format. Possible access methods are HTTP (http://host:port/path), or plain TCP (tcp://host:port/path). If the host address is an IPv6 address, it must be enclosed in square brackets (http://[IPv6-address]:port/).

name

Optionally specifies the destination CA name for the operation, in case a CA certificate was not given using the option –C.

Examples

Initial Certificate Enrollment

This example provides commands for enrolling an initial certificate for digital signature use. It generates a private key into a PKCS #8 plaintext file named initial.prv, and stores the enrolled certificate into file initial-0.crt. The user is authenticated to the CA with the key identifier (refnum) 62154 and the key ssh. The subject name and alternative IP address are given, as well as key-usage flags. The CA address is pki.ssh.com, the port 8080, and the CA name to access Test CA 1.

$ ssh-cmpclient-g3 INITIALIZE \
   -P generate://pkcs8@rsa:2048/initial -o initial \
   -p 62154:ssh \n   -s 'C=FI,O=SSH,CN=Example/initial;IP=1.2.3.4' \n   -u digitalsignature \n   http://pki.ssh.com:8080/pkix/ \n   'C=FI, O=SSH Communications Security Corp, CN=SSH Test CA 1 No Liabilities'

As a response the command presents the issued certificate to the user, and the user accepts it by typing yes at the prompt.

Certificate =
  SubjectName = <C=FI, O=SSH, CN=Example/initial>
  IssuerName = <C=FI, O=SSH Communications Security Corp, 
               CN=SSH Test CA 1 No Liabilities>
Key update

Before the certificate expires, a new certificate with updated validity period should be enrolled. **ssh-cmpclient-g3** supports key update, where a new private key is generated and the key update request is authenticated with the old (still valid) certificate. The old certificate is also used as a template for issuing the new certificate, so the identity of the user will not be changed during the key update. With the following command you can update the key pair, which was enrolled in the previous example. Presenting the resulting certificate has been left out.

```bash
$ ssh-cmpclient-g3 UPDATE \
  -k initial.prv -c initial-0.crt -P \n  generate://pkcs8@rsa:2048/updatedcert -o updatedcert \n  http://pki.ssh.com:8080/pkix/ \n  "C=FI, O=SSH Communications Security Corp, CN=SSH Test CA 1 No Liabilities"
```

The new key pair can be found in the files with the `updatedcert` prefix. The policy of the issuing CA needs to also allow automatic key updates if **ssh-cmpclient-g3** is used in the `UPDATE` mode.
ssh-scepclient-g3

ssh-scepclient-g3 — SCEP enrollment client

Synopsis

ssh-scepclient-g3 command [options] access [name]

Where command is one of the following:

   GET-CA
   GET-CHAIN
   ENROLL psk keypair template

Most commands can accept the following options:

   -o prefix       Save result into files with prefix.
   -S url          Use this socks server to access CA.
   -H url          Use this HTTP proxy to access CA.

The following identifiers are used to specify options:

   psk       -p key (used as revocationPassword or challengePassword)
   keypair   -P url (private-key URL)
   ca        -C file (CA certificate file)
   -E file (RA encryption certificate file)
   -V file (RA validation certificate file)
   template  -T file (certificate template)
   -s subject-ldap[type=value]
   -u key-usage-name[key-usage-name]
   -U extended-key-usage-name[extended-key-usage-name]
   access    URL where the CA listens for requests.

GET-CA and GET-CHAIN take name argument, that is something interpreted by the CA to specify a CA entity managed by the responder.

Key URLs are either valid external key paths or in the format:

   "generate://savetype:password@keytype:size/save-file-prefix"
   "file://savetype:password@/file-prefix"
   "file://passphrase/file-prefix"
   "file:/file-prefix"
   "key-filename"

The "keytype" for the SCEP protocol has to be "rsa".

The key generation "savetype" can be:

   - ssh2 (Secure Shell 2 key type)
   - ssh1 (Legacy Secure Shell 1 key type)
   - ssh (Tectia proprietary crypto library format, passphrase-protected)
   - pkcs1 (PKCS#1 format)
   - pkcs8s (passphrase-protected PKCS#8, "shrouded PKCS#8")
   - pkcs8 (plain-text PKCS#8)
   - x509 (Tectia proprietary X.509 library key type)
Description

The `ssh-scepclient-g3` command-line tool (`ssh-scepclient-g3.exe` on Windows) is a certificate enrollment client that uses the SCEP protocol. It can generate an RSA public-key pair and get certificates for its public components. The SCEP protocol was developed by Cisco and Verisign to be used on Cisco routers. Nowadays most CA platforms support this protocol for client certificate enrollment.

Commands

The `ssh-scepclient-g3` command-line command keywords are listed below. Shorthands longer than three letters can be used to identify the command. The commands are case-insensitive. The user must specify the CA address URL for each command. Here the term "user" refers to a user, program, or hardware device.

GET-CA

Requests CA or RA certificate download from the CA, and display the certificate fingerprint for CA validation. Fingerprints should be received from the CA using some out-of-band mechanism.

GET-CHAIN

Requests certificate chain from the CA/RA to the top-level CA.

ENROLL

Requests a new certificate from the CA. The CA will authorize the request using some out-of-band mechanism, or it can contain a password received from the CA.

Options

-o prefix

Saves output certificates into files with the given prefix. The prefix is first appended by a number, followed by the file extension `.ca` for CA certificates or `.crt` for user certificates.

-S url

Specifies the SOCKS URL if the CA is located behind a SOCKS-enabled firewall. The format of the URL is: `socks://[username@]server[:port][/network/bits[,network/bits]]`

-H url

Uses the given HTTP proxy server to access the CA. The format of the URL is: `http://server[:port]/`.

The usage line uses the following meta commands:

psk

The pre-shared key given by the CA or RA, or a revocation password invented by the client and provided to the CA when the user wishes to revoke the certificate issued. The type and need for this depends on the PKI platform used by the CA.
-p key

An authentication password or a revocation password transferred (in encrypted format) to the CA for certification request or revocation request authorization purposes.

keypair

The subject key pair to be certified.

-P url

URL specifying the private key location. This is an external key URL whose format is specified in the section called “Synopsis”.

c a

The CA/RA certificates.

-C file

When performing enrollment, reads the CA certificate from the given file path.

-E file

Optionally specifies the RA encryption certificate.

-V file

Optionally specifies the RA signing certificate.

t e m p l a t e

The subject name and flags to be certified.

-T file

The file containing the certificate used as the template for the operation. Values used to identify the subject are read from this, but the user may overwrite the key, key-usage flags, or subject names.

-s subject-ldap[type=value]*

A subject name in reverse LDAP format, that is, the most general component first, and alternative subject names. The name subject-ldap will be copied into the request verbatim.

A typical choice would be a DN in the format "C=US,O=SSH,CN=Some Body", but in principle this can be anything that is usable for the resulting certificate.

The possible type values are ip, email, dn, dns, uri, and rid.

-u key-usage-name[key-usage-name]*

Requested key usage purpose code. The following codes are recognized: digitalSignature, nonRepudiation, keyEncipherment, dataEncipherment, keyAgreement, keyCertSign,
cRLSign, encipherOnly, decipherOnly, and help. The special keyword help lists the supported key usages which are defined in RFC 3280.

\[-U \text{extended-key-usage-name[;extended-key-usage-name]}\]*

Requested extended key usage code. The following codes, in addition to user-specified dotted OID values are recognized: serverAuth, clientAuth, codeSigning, emailProtection, timeStamping, ikeIntermediate, and smartCardLogon.

access

Specifies the address of the CA in URL format. If the host address is an IPv6 address, it must be enclosed in brackets (http://[IPv6-address]:port/).

name

Specifies the destination CA name.

Examples

In the following example we first receive the CA certificate. The CA address is pki.ssh.com, the port is 8080, and the CA name is test-cal.ssh.com.

```
$ ssh-scepclient-g3 GET-CA
   -o ca http://pki.ssh.com:8080/scep/
   test-cal.ssh.com

Received CA/RA certificate ca-0.ca:

```

Next, we enroll an RSA certificate. The user is authenticated to the CA with the key ssh. The subject name and alternative IP address are given, as well as key-usage flags.

```
$ ssh-scepclient-g3 ENROLL
   -C ca-0.ca -p ssh
   -o subject -P generate://pkcs8:ssh@rsa:2048/subject
   -s 'C=FI,O=SSH,CN=SCEP Example;IP=1.2.3.4' 
   -u digitalsignature
   http://pki.ssh.com:8080/scep/

Received user certificate subject-0.crt:

```

$ ls subject*

subject-0.crt  subject.prv
ssh-certview-g3

ssh-certview-g3 — certificate viewer

Synopsis

ssh-certview-g3
[options...] file
[options...] file ...

Description

The ssh-certview-g3 program (ssh-certview-g3.exe on Windows) is a simple command-line application, capable of decoding and showing X.509 certificates, CRLs, and certification requests. The command output is written to the standard output.

Options

The following options are available:

-h

Displays a short help.

-verbose

Gives more diagnostic output.

-quiet

Gives no diagnostic output.

-auto

The next input file type is auto-detected (default).

-cert

The next input file is a certificate.

-certpair

The next input file is a cross-certificate pair.

-crmf

The next input file is a CRMF certification request.
-req
The next input file is a PKCS #10 certification request.

-crl
The next input file is a CRL.

-prv
The next input file is a private key.

-pkcs12
The next input file is a PKCS#12 package.

-ssh2
The next input file is an SSH2 public key.

-spkac
The next input file is a Netscape-generated SPKAC request.

-noverify
Does not check the validity of the signature on the input certificate.

-autoenc
Determines PEM/DER automatically (default).

-pem
Assumes that the input file is in PEM (ASCII base-64) format. This option allows both actual PEM (with headers and footers), and plain base-64 (without headers and footers). An example of PEM header and footer is shown below:

```
-----BEGIN CERTIFICATE-----
encoded data
-----END CERTIFICATE-----
```

-der
Assumes that the input file is in DER format.

-hexl
Assumes that the input file is in Hexl format. (Hexl is a common Unix tool for outputting binary files in a certain hexadecimal representation.)

-skip number
Skips number bytes from the beginning of input before trying to decode. This is useful if the file contains some garbage before the actual contents.
-ldap

Prints names in LDAP order.

-utf8

Prints names in UTF-8.

-latin1

Prints names in ISO-8859-1.

-base10

Outputs big numbers in base-10 (default).

-base16

Outputs big numbers in base-16.

-base64

Outputs big numbers in base-64.

-width number

Sets output width (number characters).

Example

For example, using a certificate downloaded from pki.ssh.com, when the following command is given:

```bash
$ ssh-certview-g3 -width 70 ca-certificate.cer
```

The following output is produced:

```
Certificate =
    SubjectName = <C=FI, O=SSH Communications Security Corp, CN=Secure Shell Test CA>
    IssuerName = <C=FI, O=SSH Communications Security Corp, CN=Secure Shell Test CA>
    SerialNumber= 34679408
    SignatureAlgorithm = rsa-pkcs1-shal
    Certificate seems to be self-signed.
        * Signature verification success.
    Validity =
    NotBefore = 2003 Dec  3rd, 08:04:27 GMT
    NotAfter  = 2005 Dec  2nd, 08:04:27 GMT
    PublicKeyInfo =
        PublicKey =
            Algorithm name (SSH) : if-modn{sign{rsa-pkcs1-md5}}
            Modulus n (1024 bits) :

**ssh-ekview-g3**

ssh-ekview-g3 — external key viewer

**Synopsis**

`ssh-ekview-g3 [options...] provider`

**Description**

The **ssh-ekview-g3** program (**ssh-ekview-g3.exe** on Windows) allows you to export certificates from external key providers. You can further study these certificates with **ssh-certview-g3**.

This is useful when you want to generate, for example, entries for allowing certificate authentication in the **ssh-server-config.xml** file. You might need to know the subject names on the certificate.

With **ssh-ekview-g3**, you can export the certificate and get the information you need from the certificates with **ssh-certview-g3**.

**Options**

The following options are available:

- **-h**
  
  Displays a short help.

- **-i info**
  
  Uses `info` as the initialization string for the provider.

- **-k**
  
  Prints the key paths only.

- **-e keypath**
  
  Exports certificates at `keypath` to files.

- **-a**
  
  Exports all found certificates to files.

- **-b base**
  
  Uses `base` when printing integers. For example, the decimal 10 is 'a' in base-16.
Appendix D Egrep Syntax

The Tectia tunneling filter rules can be matched to hostname or IP address patterns specified using the \texttt{egrep} syntax. In addition, regular expressions can be used in selectors when specifying ranges of values. The egrep syntax is explained in this section.

D.1 Egrep Patterns

The escape character is a backslash (\). You can use it to escape meta characters to use them in their plain character form.

In the following examples literal ‘E’ and ‘F’ denote any expression, whether a pattern or a character.

\[
\begin{align*}
( & \quad \text{Start a capturing subexpression.} \\
) & \quad \text{End a capturing subexpression.} \\
E|F & \quad \text{Disjunction, match either E or F (inclusive). E is preferred if both match.} \\
E^* & \quad \text{Act as Kleene star, match E zero or more times.} \\
E^+ & \quad \text{Closure, match E one or more times.}
\end{align*}
\]

E?

Option, match E optionally once.

.

Match any character except for newline characters (\n, \f, \r) and the NULL byte.

E{n}

Match E exactly n times.

E{n,} or E{n,0}

Match E n or more times.

E{,n} or E{0,n}

Match E at most n times.

E{n,m}

Match E no less than n times and no more than m times.

[

Start a character set, see Section D.3.

$

Match the empty string at the end of the input or at the end of a line.

^$

Match the empty string at the start of the input or at the beginning of a line.

### D.2 Escaped Tokens for Regex Syntax Egrep

\0n..n

The literal byte with octal value n..n.

\0

The NULL byte.

\[1-9].x

The literal byte with decimal value \{1–9\}..x.

\xn..n or \0xn..n

The literal byte with hexadecimal value n..n.
\<

Match the empty string at the beginning of a word.

\>

Match the empty string at the end of a word.

\b

Match the empty string at a word boundary.

\B

Match the empty string provided it is not at a word boundary.

\w

Match a word-constituent character, equivalent to [a-zA-Z0-9-].

\W

Match a non-word-constituent character.

\a

Literal alarm character.

\e

Literal escape character.

\f

Literal line feed.

\n
Literal new line, equivalent to C’s ‘\n’ so it can be more than one character long.

\r

Literal carriage return.

\t

Literal tab.

All other escaped characters denote the literal character itself.

**D.3 Character Sets For Egrep**
A character set starts with '[' and ends at non-escaped ']' that is not part of a POSIX character set specifier and that does not follow immediately after ']'.

The following characters have a special meaning and need to be escaped if meant literally:

- (minus sign)

  A range operator, except immediately after '[', where it loses its special meaning.

^  

  If immediately after the starting '[', denotes a complement: the whole character set will be complemented. Otherwise literal '^'.

[:alnum:]

  Characters for which 'isalnum' returns true.

[:alpha:]

  Characters for which 'isalpha' returns true.

[:cntrl:]

  Characters for which 'iscntrl' returns true.

[:digit:]

  Characters for which 'isdigit' returns true.

[:graph:]

  Characters for which 'isgraph' returns true.

[:lower:]

  Characters for which 'islower' returns true.

[:print:]

  Characters for which 'isprint' returns true.

[:punct:]

  Characters for which 'ispunct' returns true.

[:space:]

  Characters for which 'isspace' returns true.

[:upper:]

  Characters for which 'isupper' returns true.
[:xdigit:]  

Characters for which 'isxdigit' returns true.

**Example:** `[:xdigit:]XY` is typically equivalent to `[0123456789ABCDEFabcdefXY]`.

It is also possible to include the predefined escaped character sets into a newly defined one, so `[^d\s]` matches digits and whitespace characters.

Also, escape sequences resulting in literals work inside character sets.
Appendix E Audit Messages

This appendix lists the audit messages generated by the Connection Broker.

1000 KEX_failure
Level: warning
Origin: Tectia Server, Connection Broker

The key exchange failed.

<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text</td>
<td>Error details</td>
</tr>
</tbody>
</table>

**1118 CM_http_search_started**
The certificate validation subsystem is initiating a search for a CRL or a sub-CA through the HTTP protocol.

Default log facility: normal

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text</td>
<td>Search target</td>
</tr>
</tbody>
</table>

**1119 CM_http_search_success**

Level: informational
Origin: Tectia Server, Connection Broker

An HTTP request for a CRL or a sub-CA completed successfully.

Default log facility: normal

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text</td>
<td>Status message detailing what was being retrieved</td>
</tr>
</tbody>
</table>

**1120 CM_http_search_failure**

Level: informational
Origin: Tectia Server, Connection Broker

An HTTP request for a CRL or a sub-CA failed.

Default log facility: normal

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>

Tectia® Client 6.4 User Manual  
© 1995–2021 SSH Communications Security Corporation
Appendix F Removing OpenSSL from Tectia Client

F.1 Background Information

F.1.1 OpenSSL in Tectia

Tectia products contain the full OpenSSL cryptographic library "crypto", but only the algorithms provided by the fipscanister object are used.

F.1.2 Should I Remove the OpenSSL Library?

When Tectia Client is not used in the FIPS compliant mode (for more information, see Section 3.6), the OpenSSL cryptographic library is not needed and can be removed.

If you do not use the FIPS mode and want to remove OpenSSL from your Tectia Client installation, the following sections provide per-platform instructions for doing it.

F.1.3 What Happens If I Remove the OpenSSL Library?

Once the OpenSSL cryptographic library is removed, if Tectia Client is configured to run in the FIPS compliant mode, it will refuse to start.

F.2 Removing the OpenSSL Cryptographic Library

F.2.1 Unix

To remove the OpenSSL cryptographic library from Tectia Client on Unix, delete the files that are listed in the following for your operating system.
Note that in the file names:

- \( <a>, <b> \) and \( <c> \) indicate the OpenSSL version number, for example 1.0.0
- \( <x>, <y>, <z> \) and \( <b> \) indicate the Tectia Client product release version and build numbers, for example 6.4.99.123.

**Linux, Oracle Solaris and HP-UX (IA-64)**

To remove OpenSSL from Tectia Client on Linux, Oracle Solaris or HP-UX (IA-64), delete the following files:

- `/opt/tectia/lib/shlib/libcrypto.so.<a>.<b>.<c>`
- `/opt/tectia/lib/sshsecsh/<x>.<y>.<z>.<b>/libsshcrypto-fips.so`

**IBM AIX**

To remove OpenSSL from Tectia Client on IBM AIX, delete the following files:

- `/opt/tectia/lib/shlib/libcrypto.a`
- `/opt/tectia/lib/sshsecsh/<x>.<y>.<z>.<b>/libsshcrypto-fips.so`

**HP-UX (PA-RISC)**

To remove OpenSSL from Tectia Client on HP-UX (PA-RISC), delete the following files:

- `/opt/tectia/lib/shlib/libcrypto.sl.<a>.<b>.<c>`
- `/opt/tectia/lib/sshsecsh/<x>.<y>.<z>.<b>/libsshcrypto-fips.so`

**F.2.2 Windows**

Note that \(<INSTALLDIR>\) indicates the default Tectia installation directory on Windows:

- **On 32-bit Windows versions**: `C:\Program Files\SSH Communications Security\SSH Tectia`
- **On 64-bit Windows versions**: `C:\Program Files (x86)\SSH Communications Security\SSH Tectia`

To remove OpenSSL from Tectia Client on Windows, delete the following files:

- `\<INSTALLDIR>\SSH Tectia AUX\Plugins\<x>.<y>.<z>.<b>\sshcrypto1.dll`
- `\<INSTALLDIR>\SSH Tectia AUX\libeay32.dll`
- `\<INSTALLDIR>\SSH Tectia Client\libeay32.dll`

GNU LESSER GENERAL PUBLIC LICENSE

Version 3, 29 June 2007

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

This version of the GNU Lesser General Public License incorporates the terms and conditions of version 3 of the GNU General Public License, supplemented by the additional permissions listed below.

0. Additional Definitions.

As used herein, “this License” refers to version 3 of the GNU Lesser General Public License, and the “GNU GPL” refers to version 3 of the GNU General Public License.

“The Library” refers to a covered work governed by this License, other than an Application or a Combined Work as defined below.

An “Application” is any work that makes use of an interface provided by the Library, but which is not otherwise based on the Library. Defining a subclass of a class defined by the Library is deemed a mode of using an interface provided by the Library.
A “Combined Work” is a work produced by combining or linking an Application with the Library. The particular version of the Library with which the Combined Work was made is also called the “Linked Version”.

The “Minimal Corresponding Source” for a Combined Work means the Corresponding Source for the Combined Work, excluding any source code for portions of the Combined Work that, considered in isolation, are based on the Application, and not on the Linked Version.

The “Corresponding Application Code” for a Combined Work means the object code and/or source code for the Application, including any data and utility programs needed for reproducing the Combined Work from the Application, but excluding the System Libraries of the Combined Work.

1. Exception to Section 3 of the GNU GPL.

You may convey a covered work under sections 3 and 4 of this License without being bound by section 3 of the GNU GPL.

2. Conveying Modified Versions.

If you modify a copy of the Library, and, in your modifications, a facility refers to a function or data to be supplied by an Application that uses the facility (other than as an argument passed when the facility is invoked), then you may convey a copy of the modified version:

• a) under this License, provided that you make a good faith effort to ensure that, in the event an Application does not supply the function or data, the facility still operates, and performs whatever part of its purpose remains meaningful, or

• b) under the GNU GPL, with none of the additional permissions of this License applicable to that copy.

The object code form of an Application may incorporate material from a header file that is part of the Library. You may convey such object code under terms of your choice, provided that, if the incorporated material is not limited to numerical parameters, data structure layouts and accessors, or small macros, inline functions and templates (ten or fewer lines in length), you do both of the following:

• a) Give prominent notice with each copy of the object code that the Library is used in it and that the Library and its use are covered by this License.

• b) Accompany the object code with a copy of the GNU GPL and this license document.

You may convey a Combined Work under terms of your choice that, taken together, effectively do not restrict modification of the portions of the Library contained in the Combined Work and reverse engineering for debugging such modifications, if you also do each of the following:

• a) Give prominent notice with each copy of the Combined Work that the Library is used in it and that the Library and its use are covered by this License.
• b) Accompany the Combined Work with a copy of the GNU GPL and this license document.

• c) For a Combined Work that displays copyright notices during execution, include the copyright notice for the Library among these notices, as well as a reference directing the user to the copies of the GNU GPL and this license document.

• d) Do one of the following:
  
  • 0) Convey the Minimal Corresponding Source under the terms of this License, and the Corresponding Application Code in a form suitable for, and under terms that permit, the user to recombine or relink the Application with a modified version of the Linked Version to produce a modified Combined Work, in the manner specified by section 6 of the GNU GPL for conveying Corresponding Source.

  • 1) Use a suitable shared library mechanism for linking with the Library. A suitable mechanism is one that (a) uses at run time a copy of the Library already present on the user's computer system, and (b) will operate properly with a modified version of the Library that is interface-compatible with the Linked Version.

  • 2) Convey the work in copyright, with the required copyright notice, documentation, etc., and a copy of the License, under terms that permit the most广泛 distribution and modification to the Library.

  • e) Provide Installation Information, but only if you would otherwise be required to provide such information under section 6 of the GNU GPL, and only to the extent that such information is necessary to install and execute a modified version of the Combined Work produced by recombining or relinking the Application with a modified version of the Linked Version. (If you use option 4d0, the Installation Information must accompany the Minimal Corresponding Source and Corresponding Application Code. If you use option 4d1, you must provide the Installation Information in the manner specified by section 6 of the GNU GPL for conveying Corresponding Source.)

You may place library facilities that are a work based on the Library side by side in a single library together with other library facilities that are not Applications and are not covered by this License, and convey such a combined library under terms of your choice, if you do both of the following:

• a) Accompany the combined library with a copy of the same work based on the Library, uncombined with any other library facilities, conveyed under the terms of this License.

• b) Give prominent notice with the combined library that part of it is a work based on the Library, and explaining where to find the accompanying uncombined form of the same work.

6. Revised Versions of the GNU Lesser General Public License.

The Free Software Foundation may publish revised and/or new versions of the GNU Lesser General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Library as you received it specifies that a certain numbered version of the GNU Lesser General Public License “or any later version” applies to it, you have the option of following the terms and conditions either of that published version or of
any later version published by the Free Software Foundation. If the Library as you received it does not specify a version number of the GNU Lesser General Public License, you may choose any version of the GNU Lesser General Public License ever published by the Free Software Foundation.

If the Library as you received it specifies that a proxy can decide whether future versions of the GNU Lesser General Public License shall apply, that proxy's public statement of acceptance of any version is permanent authorization for you to choose that version for the Library.
